## ABSTRACT

### Background

Management of severe acute malnutrition (SAM) in children comprises two potential phases: stabilisation and rehabilitation. During the initial stabilisation phase, children receive treatment for dehydration, electrolyte imbalances, intercurrent infections and other complications. In the rehabilitation phase (applicable to children presenting with uncomplicated SAM or those with complicated SAM after complications have been resolved), catch-up growth is the main focus and the recommended energy and protein requirements are much higher. In-hospital rehabilitation of children with SAM is not always desirable or practical - especially in rural settings - and home-based care can offer a better solution. Ready-to-use therapeutic food (RUTF) is a widely used option for home-based rehabilitation, but the findings of our previous review were inconclusive.

### Objectives

To assess the effects of home-based RUTF used during the rehabilitation phase of SAM in children aged between six months and five years on recovery, relapse, mortality and rate of weight gain.

### Search methods

We searched the following databases in October 2018: CENTRAL, MEDLINE, Embase, six other databases and three trials registers. We ran separate searches for cost-effectiveness studies, contacted researchers and healthcare professionals in the field, and checked bibliographies of included studies and relevant reviews.

### Selection criteria

Randomised controlled trials (RCTs) and quasi-RCTs, where children aged between six months and five years with SAM were, during the rehabilitation phase, treated at home with RUTF compared to an alternative dietary approach, or with different regimens and formulations of RUTF compared to each other. We assessed recovery, deterioration or relapse and mortality as primary outcomes; and rate of weight gain, time to recovery, anthropometrical changes, cognitive development and function, adverse outcomes and acceptability as secondary outcomes.

## Data collection and analysis

We screened for eligible studies, extracted data and assessed risk of bias of those included, independently and in duplicate. Where data allowed, we performed a random-effects meta-analysis using Review Manager 5, and investigated substantial heterogeneity through subgroup and sensitivity analyses. For the main outcomes, we evaluated the quality of the evidence using GRADE, and presented results in a 'Summary of findings' table per comparison.

## Main results

We included 15 eligible studies ( $n = 7976$ ; effective sample size = 6630), four of which were cluster trials. Eight studies were conducted in Malawi, four in India, and one apiece in Kenya, Zambia, and Cambodia. Six studies received funding or donations from industry whereas eight did not, and one study did not report the funding source.

The overall risk of bias was high for six studies, unclear for three studies, and low for six studies. Among the 14 studies that contributed to meta-analyses, none ( $n = 5$ ), some ( $n = 5$ ) or all ( $n = 4$ ) children were stabilised in hospital prior to commencement of the study. One small study included only children known to be HIV-infected, another study stratified the analysis for 'recovery' according to HIV status, while the remaining studies included HIV-uninfected or untested children. Across all studies, the intervention lasted between 8 and 16 weeks. Only five studies followed up children postintervention (maximum of six months), and generally reported on a limited number of outcomes.

We found seven studies with 2261 children comparing home-based RUTF meeting the World Health Organization (WHO) recommendations for nutritional composition (referred to in this review as standard RUTF) with an alternative dietary approach (effective sample size = 1964). RUTF probably improves recovery (risk ratio (RR) 1.33; 95% confidence interval (CI) 1.16 to 1.54; 6 studies, 1852 children; moderate-quality evidence), and may increase the rate of weight gain slightly (mean difference (MD) 1.12 g/kg/day, 95% CI 0.27 to 1.96; 4 studies, 1450 children; low-quality evidence), but we do not know the effects on relapse (RR 0.55, 95% CI 0.30 to 1.01; 4 studies, 1505 children; very low-quality evidence) and mortality (RR 1.05, 95% CI 0.51 to 2.16; 4 studies, 1505 children; very low-quality evidence).

Two quasi-randomised cluster trials compared standard, home-based RUTF meeting total daily nutritional requirements with a similar RUTF but given as a supplement to the usual diet (213 children; effective sample size = 210). Meta-analysis showed that standard RUTF meeting total daily nutritional requirements may improve recovery (RR 1.41, 95% CI 1.19 to 1.68; low-quality evidence) and reduce relapse (RR 0.11, 95% CI 0.01 to 0.85; low-quality evidence), but the effects are unknown for mortality (RR 1.36, 95% CI 0.46 to 4.04; very low-quality evidence) and rate of weight gain (MD 1.21 g/kg/day, 95% CI - 0.74 to 3.16; very low-quality evidence).

Eight studies randomised 5502 children (effective sample size = 4456) and compared standard home-based RUTF with RUTFs of alternative formulations (e.g. using locally available ingredients, containing less or no milk powder, containing specific fatty acids, or with added pre- and probiotics). For recovery, it made little or no difference whether standard or alternative formulation RUTF was used (RR 1.03, 95% CI 0.99 to 1.08; 6 studies, 4188 children; high-quality evidence). Standard RUTF decreases relapse (RR 0.84, 95% CI 0.72 to 0.98; 6 studies, 4188 children; high-quality evidence). However, it probably makes little or no difference to mortality (RR 1.00, 95% CI 0.80 to 1.24; 7 studies, 4309 children; moderate-quality evidence) and may make little or no difference to the rate of weight gain (MD 0.11 g/kg/day, 95% CI -0.32 to 0.54; 6 studies, 3807 children; low-quality evidence) whether standard or alternative formulation RUTF is used.

## Authors' conclusions

Compared to alternative dietary approaches, standard RUTF probably improves recovery and may increase rate of weight gain slightly, but the effects on relapse and mortality are unknown. Standard RUTF meeting total daily nutritional requirements may improve recovery and relapse compared to a similar RUTF given as a supplement to the usual diet, but the effects on mortality and rate of weight gain are not clear. When comparing RUTFs with different formulations, the current evidence does not favour a particular formulation, except for relapse, which is reduced with standard RUTF. Well-designed, adequately powered, pragmatic RCTs with standardised outcome measures, stratified by HIV status, and that include diarrhoea as an outcome, are needed.

## PLAIN LANGUAGE SUMMARY

### Ready-to-use therapeutic food (RUTF) as home-based treatment for severely malnourished children between six months and five years

Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age (Review)

2

## Background

Malnourished children usually look very thin or wasted and they have a high risk of death and illness. Treating severely malnourished children in hospitals is not always desirable or practical in rural settings, and home-based treatment may be better. Home-based treatment can be food prepared by a caregiver (such as flour porridge or energy- and nutrient-dense locally available foods), or ready-to-use therapeutic food (RUTF) provided by a clinic. RUTF is usually made according to a standard, energy-rich composition defined by the World Health Organization (WHO). Typically, the ingredients for standard RUTF include milk powder, sugar, peanut butter, vegetable oil, vitamins and minerals; but ingredients vary depending on local availability, cost and acceptability. Benefits of RUTF include a long shelf life without refrigeration and they require no preparation. This is an update of our previous review, where definite conclusions about the effects of RUTF could not be drawn from the four studies that were available at that time.

## Review question

We assessed standard RUTF compared to an alternative dietary approach (e.g. flour porridge or locally available foods) and examined whether smaller amounts and different formulations of RUTF can achieve similar health outcomes in severely malnourished children aged between six months and five years. The main health outcomes that we investigated were recovery from severe malnutrition, deterioration or relapse, death and the rate of weight gain.

## Included study characteristics

We searched databases for studies up to the October 2018, and found 15 studies with 7976 children. Eight studies were conducted in Malawi, four in India, and one apiece in Kenya, Zambia, and Cambodia. One small study included only children infected with HIV, another study analysed children with and without HIV separately for the main outcome (recovery), while the other studies included children who were not infected with HIV or who were untested. Overall, we judged six studies to be at high risk of bias, three studies to be at unclear risk of bias, and six studies to be at low risk of bias. (With 'risk of bias', we mean the extent to which the methods used in a study enable it to determine the truth.) All the studies lasted between 8 and 16 weeks. Only five studies followed up children after the study (for a maximum of six months), and generally reported on a limited number of outcomes.

Of our 15 included studies, six were linked to funding or donations from industry, one did not report the source of funding, and eight studies reported funding where sponsors did not include industry.

## Key findings

Compared to alternative dietary approaches, standard RUTF probably improves recovery (moderate-quality evidence) and may increase the rate of weight gain slightly (low-quality evidence), but the effects on relapse and death are unknown (very low-quality evidence). With 'quality of evidence' we mean how confident we are that the particular finding represents the true effect. For example, 'very low-quality' means we are very uncertain about the finding, 'low-quality evidence' means the future research is *very likely* to change the finding, 'moderate-quality evidence' means that future studies *may* change this finding, and 'high-quality evidence' means that it is *unlikely* that future studies will change the finding.

Standard RUTF meeting total daily nutritional requirements may improve recovery and relapse compared to a similar RUTF given supplementary to the usual diet (low-quality evidence), but for death and the rate of weight gain, the effects are not known (very low-quality evidence).

When comparing RUTFs of different formulations, it makes little or no difference for recovery whether a standard or alternative formulation RUTF is used (high-quality evidence). For relapse, using standard RUTF decreases relapse (high-quality evidence). It probably makes little or no difference to death (moderate-quality evidence) and to the rate of weight gain (low-quality evidence) whether standard or alternative formulation RUTF is used.

Well-designed, randomised controlled trials (experimental studies where participants meeting the inclusion criteria have an equal chance of being allocated to any of the intervention or control groups) in which analyses have been performed separately for children with and without HIV, and that also measure and report on diarrhoea occurrence, are needed.

## SUMMARY OF FINDINGS FOR THE MAIN COMPARISON *[Explanation]*

**CI:** confidence interval; **RCT:** randomised controlled trial; **RR:** risk ratio; **RUTF:** ready-to-use therapeutic food; **SAM:** severe acute malnutrition; **WHZ:** weight-for-age z score

#### GRADE Working Group grades of evidence

**High quality:** further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** we are very uncertain about the estimate.

<sup>a</sup>Downgraded by one level for risk of bias: three studies judged to have a high risk of selection bias, and one study judged to have a high risk of attrition and other bias.

<sup>b</sup>Downgraded by one level for indirectness: significant difference between subgroups based on whether all or some children were stabilised in hospital before the trial.

<sup>c</sup>Downgraded by one level for risk of bias: three studies judged to have a high risk of selection bias.

<sup>d</sup>Downgraded by one level for inconsistency:  $I^2$  statistic is more than 50%.

<sup>e</sup>Downgraded by one level for imprecision: 95% CI includes both an important benefit and harm.

## BACKGROUND

### Description of the condition

Malnutrition occurs when the quantity of one or more macronutrients available to the body is inadequate to sustain optimal bodily functions (undernutrition) or when an excessive amount of energy is consumed (overnutrition); this is often accompanied by micronutrient deficiencies (Manary 2008). Malnutrition in infants and young children may present as stunting, wasting, overweight or obesity (UNICEF/WHO/WBG 2017). Stunting and wasting refer to undernutrition, while overweight and obesity are manifestations of overnutrition.

Stunting is a chronic form of malnutrition resulting in linear growth deficits relative to well-nourished children of the same age (UNICEF/WHO/WBG 2017). A child is defined as stunted if his or her length or height is more than two standard deviations (SD) below the median value for his or her age and sex, based on the World Health Organization (WHO) Child Growth Standards

(WHO 2008). Children whose length or height for age falls below this cut-off point may never achieve their full physical or cognitive potential (UNICEF/WHO/WBG 2017).

By contrast, wasting - the form of malnutrition that is the focus of this review - is an acute condition in which a child is too thin for his or her length or height (i.e. low weight for length or height). Acute malnutrition is classified according to severity as either moderate acute malnutrition (MAM) or severe acute malnutrition (SAM). The conceptual framework by the United Nations Children's Fund (UNICEF) shows the immediate, underlying and basic causes of child undernutrition, with its short- and long-term consequences (UNICEF 2013a). Children diagnosed with MAM or SAM have an increased risk of infectious diseases, developmental delays, and death. SAM is a particularly life-threatening condition, which requires early detection before the onset of complications, and prompt treatment (UNICEF 2013b). The initial treatment of SAM varies depending on whether it is complicated by infection, metabolic disturbances, severe oedema or poor appetite; or uncomplicated, where children are clinically well, alert and have an appetite (Figure 1).

Figure 1. Diagram depicting our review question and main subgroup analysis

In children under five years of age, MAM is defined as a weight-for-height z score (WHZ) between three and two SD below the median or between 70% and 80% of the median, or mid-upper arm circumference (MUAC) between 115 mm and 125 mm, and no oedema (Black 2008; Lazzarini 2013; WHO 2012). SAM is diagnosed when children have a combination of a WHZ of more than three SDs below the median, a MUAC of less than 115 mm, and the presence of nutritional oedema (Collins 2003; Manary 2008; WHO/UNICEF 2009). MAM or SAM without bilateral pitting oedema is referred to as marasmus, while kwashiorkor is the term used when bilateral pitting oedema is present (Manary 2008). See Table 1 for a more detailed classification system for MAM and SAM.

Although some conditions, such as HIV/AIDS, tuberculosis (TB)

and kidney failure, may contribute to the onset of undernutrition, poverty and food insecurity are by far the major causes. Undernutrition and infection often co-exist and are mutually reinforcing: undernutrition increases susceptibility to infection while infection contributes to malnutrition (Kruger 2008; Naude 2008). Infections are associated with anorexia (loss of appetite), electrolyte and metabolic imbalances (WHO 2013); fever increases energy expenditure; and diarrhoea decreases nutrient absorption and can contribute to electrolyte imbalances (WHO 2013).

Despite sustained efforts to combat malnutrition (Hawkes 2015), rates are still alarmingly high. Worldwide, 155 million children under five years of age are stunted, 52 million suffer from wasting (with an additional 17 million suffering from severe wasting) and

41 million are overweight (UNICEF/WHO/WBG 2017). Africa and Asia have the greatest share of all forms of malnutrition. Although less than half of all children under five years old live in lower-middle income countries, a disproportionate two-thirds of all stunted children and about three-quarters of all wasted children live in these countries (UNICEF/WHO/WBG 2017).

## Description of the intervention

Addressing the underlying causes of economic deprivation and inequity is, undoubtedly, the only way to eradicate undernutrition in the long term. However, specific nutritional interventions can help ameliorate the health consequences of nutritional deprivation in the interim (Black 2008), and this review focuses on one such intervention for children with SAM.

Until about two decades ago, SAM was primarily managed in hospitals, which greatly limited treatment coverage and impact (WHO/WFP/UNSCN/UNICEF 2007). To reach more children, a community-based approach, which involves timely detection and provision of treatment for those without medical complications, was developed (WHO/WFP/UNSCN/UNICEF 2007).

The treatment of SAM can be divided into two potential phases, namely stabilisation and rehabilitation. Stabilisation involves a range of clinical interventions, such as treatments for dehydration, electrolyte imbalances and infections (Ashworth 2003). In terms of nutritional support, the WHO recommends continuing breastfeeding (where applicable) along with oral or nasogastric feeds that provide 100 kCal/kg/day (418 kJ/kg/day) and a low protein intake of 1.0 to 1.5 g/kg/day. F-75, a starter, milk-based therapeutic formula with a relatively low energy (75 kCal (314 kJ)) and protein content (0.9 g per 100 mL), is typically used during the stabilisation phase (Action Against Hunger 2009; WHO/UNICEF 2009). F-75 aids in initial metabolic recovery, helping to restore electrolyte imbalances (Action Against Hunger 2009). Oedema (if present) usually starts to disappear, leading to weight loss (fluid loss).

Once the child's appetite has improved and s/he is in a stable medical condition, the rehabilitation phase starts, with catch-up growth becoming the main focus. In this phase, the recommended energy requirement is 150 to 220 kCal/kg/day (628 to 921 kJ/kg/day) and 2.0 to 6.0 g/kg/day of protein (Ashworth 2003). Traditionally, F-100 (a milk-based therapeutic diet, higher in energy (100 kCal/418 kJ) and much higher in protein (2.9 g per 100 mL) than F-75) is given as part of inpatient care to initiate weight gain (WHO 2013).

Children with complicated SAM require stabilisation as inpatients while those with uncomplicated SAM often do not need inpatient stabilisation (WHO 2013; WHO 2017b; WHO/WFP/UNSCN/UNICEF 2007). Although the approach used can differ between countries and settings, children who are stabilised in hospital usually start rehabilitation as inpatients but complete most of the rehabilitation phase at home (with follow-up in the outpatient department).

A challenge for treating children with SAM in low- and middle-income countries (LMICs) is that prolonged hospital care of children with acute malnutrition may not always be possible. In these settings ready-to-use therapeutic food (RUTF) - energy-dense foods with a low moisture content that can be eaten directly from the packaging - has been introduced for home-based treatment during the rehabilitation phase. (Because of its high energy and protein content, RUTF is not suitable for the stabilisation phase.)

RUTF, a solid or semi-solid product, was originally developed by Nutriset and the Institute for Research and Development in France, as a home-based follow-up treatment after F-100 (Bazzano 2017). Table 2 shows the nutritional contents of RUTF as recommended by the WHO, referred to in this review as standard RUTF; for example, see Table 3 for a typical peanut-based RUTF recipe.

Where RUTF is used for home-based rehabilitation, it can be provided to meet all of the nutritional requirements of a child recovering from SAM; for example, in low-income settings where food security may be a significant issue. Alternatively, RUTF may be provided for SAM children as a supplement to the usual family diet.

RUTF can be formulated and produced in various ways. It can be cheaper to produce RUTF with less or no milk powder, or more acceptable if locally or indigenous ingredients are used. Furthermore, fatty acid composition (specifically, omega-3 fatty acids) may play a role in infection and inflammation, and thus might be a beneficial ingredient in therapeutic food. Similarly, as children with SAM may have compromised gastrointestinal function, the addition of pre- and probiotics may be advantageous.

RUTF is often produced on a commercial scale, but can also be produced locally on a small scale (e.g. in an institution kitchen such as that of a research centre or clinic) with ingredients that may differ from commercially produced RUTF (Bazzano 2017). Two examples of commercially produced RUTF are a peanut-based paste called Plumpy'nut® (Nutriset, France; Table 4), and a solid biscuit made from cooked wheat called BP100® (developed by Compact, Denmark) (Collins 2004; Navarro-Colorado 2005). Both are fortified with micronutrients and have very low water activity, which discourages microbial growth (Brewster 2006; Kruger 2008; WHO/WFP/UNSCN/UNICEF 2007). Children as young as six months of age can consume RUTF with a homogenous paste texture (DFID 2009). Solid RUTF can also be soaked in clean, boiling water and eaten as porridge by young infants and as a biscuit by older children. Infants younger than six months should not be given RUTF (DFID 2009).

A total of about 10 to 15 kg of RUTF over a period of six to eight weeks is considered necessary for recovery from SAM (UNICEF 2013b; WHO/WFP/UNSCN/UNICEF 2007). RUTF as home-based rehabilitation is not recommended as stand-alone care, but rather as part of a treatment protocol that provides full medical consultation in conjunction with nutritional counselling, routine medical care (such as immunisations, essential drugs, etc.)

and referral to hospital-based treatment where needed (UNICEF 2013b).

## Challenges with the use of RUTF

RUTF, especially when made with disaccharide sucrose rather than polysaccharide dextrimaltose, has a relatively high, renal solute load (a high load of substances that need to be eradicated in the urine) (Sandige 2004). Because excretion of these solutes requires water, there are concerns that RUTF might exacerbate dehydration and increase the risk of mortality in SAM (Grellety 2000; WHO 2013). It is therefore recommended that children consuming RUTF receive additional, free water (Greiner 2014). However, this increases the risk of bacterial contamination in some settings. In 2010, when the Nutriset patent was made available in developing countries, UNICEF - the largest international procurer of RUTF (Bazzano 2017) - published manufacturing standards for RUTF production (Komrska 2010a; Komrska 2010b). UNICEF further launched competitive bidding to ensure that local suppliers were used. While this reduced the transportation time and cost, it introduced the need for additional quality assurance to ensure optimal products (UNICEF 2015a).

Recipes for RUTF do not necessarily include peanut or milk powder, although the WHO recommends that at least half of the proteins should come from a milk source (WHO/WFP/UNSCN/UNICEF 2007). Peanuts can cause allergic reactions in susceptible individuals, and are known to be at high risk for aflatoxin contamination. Milk powder on the other hand, is expensive and often needs to be imported (Collins 2004). The cost of milk powder in Malawi constitutes more than half of the final cost of the RUTF (Collins 2004). Irena 2015 reported that the removal of milk powder and the inclusion of locally available grains and pulses can reduce the cost of ingredients by about a third.

For non-commercial production of RUTF, the following basic ingredients are required (Collins 2004).

1. Staple food as the main ingredient (preferably a cereal).
2. Protein supplement from a plant or animal food (for example, beans, groundnuts, milk, meat, chicken, fish, egg). For economic reasons, legumes and oilseeds are mostly used.
3. Vitamin and mineral supplement (a vegetable or fruit, or both).
4. Energy supplement (a fat, oil or sugar) to increase the energy density.

The food safety of the production process is an important issue, with strict monitoring and careful attention needed to avoid contamination by microorganisms or other harmful substances (for example, heavy metals, pesticides, anti-nutritional factors such as phytate or protease inhibitors) (WHO/WFP/UNSCN/UNICEF 2007).

For young children diagnosed with SAM for the first time and newly exposed to RUTF, acceptability may be a problem (Greiner 2014). However, progress has been made in terms of increasing

the acceptability of RUTF; for example, by using locally grown ingredients (Weber 2016).

The demand for RUTF increased from less than 9000 metric tonne in 2009, to over 30,000 metric tonne in 2014 (Bazzano 2017; UNICEF 2015b). Yet, despite the increased demand and growing competition amongst suppliers, the price is still high (UNICEF 2015a). According to UNICEF 2013b, the cost to rehabilitate one child with SAM is around USD 100. An Ethiopian case study conducted by UNICEF in 2013 found that the purchase of RUTF accounted for approximately half of the operating costs of a community-based management programme for acute malnutrition (Bazzano 2017; UNICEF 2013c). Cost-effectiveness, however, is related to factors such as SAM prevalence, population density and coverage (UNICEF 2015a). Producing RUTF locally presents a variety of challenges, including the cost of high-quality ingredients, currency fluctuations, value-added tax and quality control (Segré 2017; UNICEF 2015a). However, there are options to address some of these challenges. One example is a programming tool developed by Weber and Callaghan, to help facilitate the manufacturing of more cost-effective, alternative RUTFs, without compromising on quality (Weber 2016). This tool also allows for incorporating cultural and religious preferences.

The use of RUTF, however, remains a controversial issue (Bazzano 2017; Greiner 2014; UNICEF 2013b). Apart from the cost of RUTF, as described above, there are concerns about commercial exploitation beyond SAM therapy (UNICEF 2013b). The increased demand for RUTF has led to expansion of the commercial product range, such as ready-to-use supplementary foods (RUSFs; for instance, lipid-based nutritional supplements (LNS)) (Greiner 2014; Lazzarini 2013). RUSFs are used in treating MAM and stunting, as well as meeting nutritional needs and preventing malnutrition (Bazzano 2017). Conflict of interest issues, with supported examples from industry, have been extensively described in Bazzano 2017.

## How the intervention might work

Recovery from SAM during the rehabilitation phase requires high energy intake accompanied by high-quality protein and micronutrients. Locally available foods, if not fortified, often do not meet the requirements of children recovering from SAM and are prone to bacterial contamination. Infants and young children can eat limited amount of food at a time (Lin 2008). Lower energy-density foods, together with a low frequency of feeding, can result in an energy intake that is insufficient to enable recovery.

RUTF, a nutrient-dense feed, has been developed to meet these increased requirements and limits the probability of bacterial contamination. The following characteristics of RUTF may contribute to its possible beneficial effects in the rehabilitation of SAM (Bazzano 2017; Briend 1999).

1. Balanced, nutritious, home-based therapy
2. Affordable, compared to facility-based rehabilitation

3. Can be eaten safely at home, even where hygienic conditions are poor (WHO/WFP/UNSCN/UNICEF 2007)
4. Long shelf life (up to two years)
5. No special storage (for example, refrigeration) or preparation required

Due to these properties, RUTF has become pivotal to the implementation of community-based programmes for the management of malnutrition.

### Why it is important to do this review

Both the WHO and UNICEF recommend the use of RUTF in the community as therapeutic feeding for outpatient rehabilitation for children with uncomplicated SAM (WHO/UNICEF 2009; see Table 5). Furthermore, the WHO is committed to ensuring the inclusion of RUTF in the essential medicine lists (WHO 2017a). RUTF and RUSFs may pose risks for undermining best nutrition practices for infants and young children, such as compromising breastfeeding after the age of six months, despite disclaimers provided by industry (Bazzano 2017; UNICEF 2013b). Furthermore, increased consumption of RUTF in a young child's diet may lead to alteration of the epigenome (which is involved in regulating gene expression and can be affected by changing environments), thereby potentially programming metabolic and physiological function throughout the life cycle (Bazzano 2017). Also, countries utilising RUTF are undergoing a nutrition transition, suffering a double burden of under- and overnutrition (Bazzano 2017). Careful consideration should therefore be given to programmes aimed at combating undernutrition, to prevent the undesirable long-term effects of overweight and obesity. In the previous version of our review (Schoonees 2013), the limited evidence-base identified precluded definitive conclusions regarding differences in clinical outcomes in children with SAM who were given home-based RUTF compared to other home-based nutritional approaches, or who received RUTF in different daily amounts or formulations. A number of new studies have since been conducted and are included in this review update. The findings of this systematic review will be of special interest to people in LMICs where SAM is a particular challenge, as well as to organisations involved in the preparation of clinical guidelines for practitioners and policy makers dealing with SAM (for example, WHO, UNICEF and government health departments).

## OBJECTIVES

To assess the effects of home-based RUTF used during the rehabilitation phase of SAM in children aged between six months and five years on recovery, relapse, mortality and rate of weight gain.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

A randomised controlled trial (RCT) is the optimal study design for answering questions about intervention effects. Because there are a number of existing RCTs that address our primary outcomes we have, as in the earlier version of this review (Schoonees 2013), included only RCTs and studies defined as quasi-randomised (that is, studies that used an inadequate method of randomisation, such as alternation or date of birth). We included studies regardless of whether the unit of randomisation was individuals or clusters (that is, studies randomised by groups such as clinics, villages or families).

#### Types of participants

Children aged between six months and five years with SAM, regardless of country, setting or disease status, and irrespective of the method of diagnosis employed.

Where a potentially eligible study included children with both SAM and MAM (or other types of malnutrition), we included studies where SAM children made up 50% or more of the randomised trial participants. Where results were not available separately for children with SAM and could not be obtained by contacting the study authors, we excluded the trial.

#### Types of interventions

##### Experimental

1. Home-based rehabilitation with standard RUTF (meeting the WHO recommendations (WHO/WFP/UNSCN/UNICEF 2007) for nutritional composition; either commercially or non-commercially produced) as total nutrition or supplement

In some settings, RUTF is provided in dosages that meet the child's full daily nutritional requirements (i.e. RUTF is the only food provided), while in other settings RUTF is given as a supplement only (i.e. caregivers are instructed that children should consume the RUTF in addition to the family's home diet). We considered both approaches in this review.

We included studies where children with SAM started F-100 or RUTF treatment in the rehabilitation phase as inpatients, provided 50% or more of the rehabilitation phase and treatment with RUTF occurred at home.

## Control

1. Dietary rehabilitation as usual (e.g. home-based foods that are often energy dense and fortified, alternative dietary approach, etc.)
2. Similar RUTF to the experimental RUTF, but used as a supplement only
3. Alternative RUTF type (i.e. RUTF differs meaningfully in terms of ingredients, nutritional content, or both)

We excluded studies in which the effects of RUTF were potentially confounded by another intervention; that is, where multiple interventions were involved, comparison groups should have received the same rehabilitation apart from the experimental RUTF. Furthermore, we excluded studies where standard (i.e. WHO-recommended), commercially produced RUTF was compared to a locally produced RUTF with similar ingredients and nutrition content.

## Types of outcome measures

### Primary outcomes

1. Recovery, during and beyond the intervention period, as defined by study authors
2. Deterioration or relapse, during and beyond the intervention period, as defined by study authors
3. Mortality, during and beyond the intervention period

### Secondary outcomes

1. Rate of weight gain, during the intervention period (to standardise weight gain across different ages, baseline weight or lengths and heights)
2. Time to recovery, during the intervention period
3. Anthropometrical status, at the end of the intervention period and beyond (assessed with, for example, WHZ, weight-for-age z score (WAZ), height-for-age z score (HAZ), MUAC)
4. Cognitive function and development, at the end of the intervention period and beyond (assessed with, for example, the Denver II (Frankenburg 1992), Bayley Scales of Infant and Toddler Development (Hoskens 2018))
5. Adverse outcomes (such as allergic reactions and diarrhoea), during and beyond the intervention period, as reported by study authors
6. Acceptability of RUTF, during the intervention period, as defined by study authors

### Economic commentary

In this update, we expanded our review by searching for studies that evaluated the cost-effectiveness of home-based RUTF as treatment for children (between six months and five years of age) with SAM.

We included studies regardless of whether they had carried out a formal cost-effectiveness assessment (i.e. whether or not the study included an effectiveness component). Furthermore, we included studies where RUTF was only one component of a community-based treatment, but reported results separately for the RUTF component.

## Search methods for identification of studies

We used a comprehensive search strategy to identify all relevant studies regardless of language or publication status. Searches for the first version of the review took place in April 2013 (Schoonees 2013). For this update, we ran searches in May and June 2017, and again in October 2018. We also expanded our search to find cost-effectiveness studies.

### Electronic searches

We searched the following databases and trials registers using the search strategies in Appendix 1.

1. Cochrane Central Register of Controlled Trials (CENTRAL; 2018, Issue 12) in the Cochrane Library (searched 9 October 2018)
  2. MEDLINE(R), Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Daily and Versions(R) Ovid (1946 to 8 October 2018)
  3. Embase Ovid (1980 to 8 October 2018)
  4. African Index Medicus ([indexmedicus.afro.who.int](http://indexmedicus.afro.who.int); searched 9 October 2018)
  5. CINAHL EBCSOhost (Cumulative Index to Nursing and Allied Health Literature; 1937 to 9 October 2018)
  6. Science Citation Index Web of Science (1970 to 9 October 2018)
  7. LILACS (Latin American and Caribbean Health Science Information database; [lilacs.bvsalud.org/en](http://lilacs.bvsalud.org/en); searched 9 October 2018)
  8. ZETOC ([zetoc.jisc.ac.uk](http://zetoc.jisc.ac.uk); limited to conference search; searched 9 October 2018)
  9. Epistemonikos ([www.epistemonikos.org](http://www.epistemonikos.org); last five years; searched 9 October 2018)
  10. ClinicalTrials.gov ([clinicaltrials.gov](http://clinicaltrials.gov); searched 10 October 2018)
  11. ISRCTN registry ([www.isrctn.com](http://www.isrctn.com); searched 9 October 2018)
  12. WHO International Clinical Trials Registry Platform (ICTRP; [apps.who.int/trialsearch](http://apps.who.int/trialsearch); searched 10 October 2018)
- We developed separate strategies to identify cost-effectiveness studies and ran them in them in the following databases (Appendix 2).
1. MEDLINE OVID (1946 to 8 October 2018)
  2. MEDLINE Epub Ahead of Print, In-Process & Other Non-Indexed Citations, Daily and Versions Ovid (1946 to 8 October 2018)

3. Embase Ovid (1947 to 8 October 2018)
4. NHS Economic Evaluation Database (NHS EED; 2015, Issue 2), part of the Cochrane Library (searched 12 June 2017; no new records added to NHS EED since March 2015)
5. ECONLIT EBSCOHost (1969 to 9 October 2018)

[Appendix 3](#) shows the search strategies used in the previous version of this review ([Schoonees 2013](#)).

### Searching other resources

We contacted researchers and healthcare professionals working in the field, sending them the list of our included and excluded studies, and asking whether they were aware of any additional studies. We also checked the reference lists of included studies, appropriate reviews and cost-effectiveness studies to identify additional studies. Furthermore, we contacted the authors of each relevant study identified in the studies registries to establish whether the study had been completed (and if so, whether or not there was a published or unpublished manuscript they could share with us), and the authors of all included studies to determine if they were aware of additional studies (published, unpublished or ongoing) in the field.

### Data collection and analysis

#### Selection of studies

Three review authors (AS, AM and ML) independently and in duplicate screened the titles and abstracts of all studies identified by the electronic searches and selected those that met the prespecified eligibility criteria ([Criteria for considering studies for this review](#)). We used the software [Covidence](#) for screening (titles and abstracts, and full-text articles) and discussed disparate judgements until we reached consensus. For studies deemed potentially eligible, we obtained the full-text reports and two review authors (AS and AM or ML) independently assessed these for eligibility. We contacted the authors of the primary studies where there was missing information or if clarification was needed. In the event of no response, or incomplete or irrelevant information being received, we categorised the study as awaiting classification ([Characteristics of studies awaiting classification](#)). We resolved any disagreements by discussion among the review authors. Two review authors (AS and AM or ML) also independently screened the results of the cost-effectiveness searches. We have presented the results of the screening process in a PRISMA flow diagram ([Moher 2009](#)). We listed studies we initially thought to be relevant but that we later excluded in the [Characteristics of excluded studies](#) tables, with reasons for exclusion.

### Data extraction and management

Three review authors (AS, ML and AM) extracted data from included studies in duplicate and independently, using a pre-piloted electronic data extraction sheet. We resolved disagreements by discussion and reaching consensus. For each included trial, we extracted information on each of the following: general (for example, ethics approval, funding and study period); methods (for example, study design and number of participants randomised per group); participants (for example, country, setting, age and comorbidity); interventions (for example, description, dose, duration, and concomitant treatment); outcomes (for example, description and time point collected); results (for example, numerical results for prespecified outcomes); and miscellaneous information (for example, testing for peanut allergies and quality of anthropometrical measurements). In addition, EN, AS and ML extracted data (one review author per trial, with AS double-checking data across studies for consistency) using the Template of Intervention Description and Replication (TIDieR) table in [Hoffmann 2017](#).

We emailed the study authors where reported information was unclear or contradictory, or where important data were missing. We entered the extracted data into one of the following tables:

1. [Characteristics of included studies](#) tables;
2. [Characteristics of excluded studies](#) tables;
3. [Characteristics of studies awaiting classification](#) tables; and
4. [Characteristics of ongoing studies](#) tables.

With the exception of data from ongoing studies, we extracted data in duplicate at all times.

We used the Cochrane Review by Sinclair and colleagues to inform our approach to presenting the data from the included cost-effectiveness studies ([Sinclair 2012](#)). One review author (EN for studies identified with the 2017 search, and AM for studies identified with the 2018 search), extracted and tabularised the data from the included studies on cost. AS double-checked the extracted data across studies for consistency. We have provided further information about the economic commentary in the [Discussion](#) section.

#### Assessment of risk of bias in included studies

Two review authors (AS and ML) independently assessed each included study for risk of bias using the guidelines provided in the *Cochrane Handbook for Systematic Reviews of Interventions* ([Higgins 2017](#)), and the criteria set out in [Appendix 4](#). They assessed studies for bias across the following domains: sequence generation, allocation concealment, blinding, incomplete outcome data, selective reporting and other potential sources of bias. For each domain, both review authors independently rated each included study at low risk of bias, high risk of bias or unclear risk of bias. They discussed any disagreements with a third review author (JV).

We evaluated cluster studies across the following, additional domains, using the specific criteria set out in [Appendix 5](#): recruitment bias, baseline imbalance, loss of clusters, incorrect analysis

and comparability with individually randomised studies (Higgins 2017).

We decided on overall risk of bias per study by taking into consideration the domains addressing selection bias, attrition bias (specifically large or differential attrition between groups) and 'other bias'.

### Measures of treatment effect

We used Review Manager 5 (RevMan 5) to manage the data and to conduct the analyses (Review Manager 2014). We calculated risk ratios (RR) for dichotomous data and mean differences (MD) for continuous data, and presented all results with 95% confidence intervals (CI). In cases where we could not extract raw data to calculate treatment effects, we reported results according to study authors.

### Unit of analysis issues

#### Cross-over trials

Because of the nature of the condition involved (SAM), we did not find any cross-over trials.

#### Cluster trials

For cluster trials, we followed the method of adjusting for clustering, described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011). None of the four included cluster trials had properly accounted for the cluster design. Therefore, we used an 'approximate method', which entailed calculation of an 'effective sample size' for the comparison groups, by dividing the original sample size by the 'design effect', which is  $1 + (c-1)ICC$ , where  $c$  is the average cluster size and  $ICC$  is the intra-cluster correlation coefficient. For dichotomous data, we divided both the number of participants and the number who experienced the event by the same design effect, while for continuous data, we adjusted only the sample size (we left means and SDs unchanged). The number of clusters was available for three of the four cluster trials and we contacted the study author of the fourth study to obtain the number of clusters (Ndekha 2005). We imputed a low  $ICC$  of 0.001 for two studies because we did not anticipate large between-cluster variability (Manary 2004; Ndekha 2005). The clusters in these studies were either the number of weeks of discharge or the days of discharge in the month. In this way, children from the same community were assessed in the same facility. We imputed a higher  $ICC$  of 0.005 for Ciliberto 2005 because seven different facilities represented seven clusters. We, therefore, expected a certain degree of between-cluster variability in this trial. Although these values might seem arbitrary, we preferred to use them to adjust the sample sizes as they are more plausible than an  $ICC$  of 0. The authors of Irena 2015 reported an  $ICC$  of 0.015, which we used to adjust the raw counts provided in the paper. We had initially

intended to use the generic inverse variance method in RevMan 5, but since we had values for the totals, means and SDs per group from each study for continuous data, it became unnecessary to do so.

### Multiple treatment groups

In three studies there were three arms that were all relevant to our review (Bhandari 2016 had two experimental RUTF arms compared to the same control; Manary 2004 and Ndekha 2005 had one experimental arm compared to two controls), and a fourth study had three arms that each included RUTF (Jones 2015). In Manary 2004 and Ndekha 2005 the experimental arm received standard RUTF in a dose that meets daily nutritional requirements whereas another arm received a similar RUTF but given as a supplement to the children's usual diet. Therefore, we could not combine these two arms into a single pair-wise comparison (Higgins 2011), and, as they relate to different comparisons, we analysed them separately. In Comparison 1, we thus selected the arm that received standard RUTF in sufficient quantity to meet daily nutritional requirements compared to the arm that received a maize and soy flour blend as intervention (adjusted for clustering using the abovementioned design effects). In Comparison 2, we also selected the arm that received standard RUTF in sufficient quantity to meet daily nutritional requirements, but compared it to the arm that received a similar RUTF but given as a supplement (adjusted for clustering using the above-mentioned design effects). Bhandari 2016, which addresses our Comparison 1, had two experimental arms that are both relevant to our question and compared it to a control of home-prepared locally available foods ("A-HPF"). The experimental interventions were "RUTF-C", which is standard RUTF prepared in a factory and "RUTF-L", which is standard RUTF that trained research staff prepared in a local site kitchen. We used both these arms in the same meta-analyses and compared it against the control group, where for dichotomous outcomes we divided the control group's number of events and sample size by two and for continuous outcomes divided the control group's sample size by two and left the means and SDs unchanged.

Jones 2015, which addresses our Comparison 3, had an arm that received standard RUTF ("S-RUTF"), an arm that received a flax seed-containing RUTF ("F-RUTF") and an arm that received the flax seed-containing RUTF plus fish oil capsules ("FFO-RUTF"). Because we could not combine the two latter arms, we chose the most appropriate comparison, which is standard RUTF versus "F-RUTF". We considered the FFO-RUTF arm not relevant to our question as the fish oil capsules were not part of the RUTF formulation and thus a potential confounding intervention.

We reported data from the latest time point during or at the end of the intervention period, and at the latest time point after the intervention period (follow-up), as stipulated in the [Types of outcome measures](#) section (unless otherwise stated). We could not group

time points as planned in our protocol (Schoonees 2011), owing to the data available (one month or less of RUTF treatment, less than one to two or more months of RUTF treatment and more than two to six months of RUTF treatment). (In hindsight, these prespecified time points are not that practical, as treatment with RUTF lasting less than two months or more than four months seldom takes place in practice.) The primary outcomes in the included studies were either measured at the time of recovery (which varied between participants and such individual data were not reported unless time to recovery was an outcome in the trial), or at the end of a predetermined time period. We did not distinguish in the analyses between such studies; however, we reported what time points were used with each outcome in each trial.

### Dealing with missing data

We attempted to obtain essential missing data (for example, standard deviations, units in which outcomes were measured, results for outcomes pre-specified but not reported, whether or not participants were stabilised in hospital before the trial, intervention duration) by contacting the study authors via email. We classified attrition per study as (1) pre-randomisation, (2) immediately post-randomisation or (3) dropouts during the intervention phase, supplemented with reasons for the absence where these were reported in the article (Table 6). We imputed values for the ICC where we could not obtain them from published data.

For dichotomous data (for example, recovery and mortality during the intervention period), we used the intention-to-treat (ITT) principle to calculate effect sizes for individual studies or to pool more than one trial. We assumed that the participants who were lost to follow-up or dropped out of the study did not experience the event of interest. However, for the outcome of 'relapse', we assumed that those who dropped out did not receive any treatment (RUTF or the control diet) and therefore experienced the event. Furthermore, when assessing dichotomous outcomes (e.g. recovery) at follow-up (e.g. six months after the children initially recovered), we employed the available-case principle; that is, we assessed only those who recovered during the intervention period and came back for follow-up, as opposed to all children who recovered. We did not consider it plausible to assume that those who did not come back deteriorated. For continuous data, we calculated MDs for studies based on the available-case principle.

### Assessment of heterogeneity

We assessed heterogeneity by visual inspection of forest plots and statistically by means of the  $\text{Chi}^2$  test for heterogeneity (significance level  $P$  value  $< 0.10$ ). We quantified heterogeneity using the  $I^2$  test (Higgins 2002), where  $I^2$  values of 50% or more indicated a substantial level of heterogeneity (Higgins 2003).

We considered the following characteristics as possible sources of clinical heterogeneity (and therefore used these in subgroup

analyses; [Subgroup analysis and investigation of heterogeneity](#)): whether or not participants were stabilised as inpatients before they received home-based RUTF; differences in RUTF (e.g. commercially produced or not); differences in age across participants, and differences in comorbidity across participants.

### Assessment of reporting biases

We had planned to assess the likelihood of reporting bias with funnel plots using at least 10 studies per comparison and outcome (Sterne 2017). However, we identified too few studies to allow for this.

### Data synthesis

We anticipated a high degree of heterogeneity due to the inclusion of children across different settings, some of whom were hospitalised before enrolment into the study and others not; intervention periods across studies being of differing duration; and the use of different definitions (e.g. for recovery and the rate of weight gain). For this reason, we used a random-effects model to combine the results per comparison and outcome across studies, with inverse-variance weighting for continuous outcomes and Mantel-Haenszel weighting for dichotomous outcomes. Where substantial statistical heterogeneity existed, we investigated the potential sources of heterogeneity through subgroup analysis as reported below ([Subgroup analysis and investigation of heterogeneity](#)).

Using the GRADE tool (Guyatt 2011), AS and ML evaluated the quality of evidence (high, moderate, low or very low) of the four most important outcomes (recovery, relapse, mortality and the rate of weight gain) for all three comparisons:

1. standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach;
2. standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet; and
3. standard RUTF versus RUTF using an alternative formulation.

We considered five reasons for possible downgrading of the quality of the evidence, namely limitations in study design or execution (risk of bias), inconsistency of results, indirectness of evidence, imprecision and publication bias. We have reported these ratings in 'Summary of findings' tables, which we created using [GRADEPro GDT 2015](#) software.

### Subgroup analysis and investigation of heterogeneity

We considered heterogeneity to be statistically significant when  $I^2$  was 50% or higher and  $P$  value was under 0.10. We performed subgroup analyses when we detected statistical heterogeneity, or, in the case of pre-trial hospitalisation, regardless of statistical heterogeneity. We considered the following subgroups.

1. Pre-trial hospital stabilisation versus no pre-trial hospitalisation: clinical heterogeneity could exist between children diagnosed with complicated SAM (requiring stabilisation in hospital) compared to those with uncomplicated SAM (who usually do not require hospitalisation)

2. Commercial (i.e. factory) versus non-commercial (i.e. institution kitchen) RUTF: it is generally cheaper to produce RUTF non-commercially in a local site kitchen than in a food factory (commercially); however, there are concerns about batch consistency and microbiological safety in the case of non-commercial production

3. Different types of RUTF products (for example, corn and soy-based versus peanut-based RUTF)

4. Age of children: 6 to 12 months, as this is the ideal period to start weaning from a milk-based diet; 13 months to 5 years, as these children consume a mixed diet (mostly not breast milk although the child may still be taking some

5. Children with or without comorbid disease (for example, HIV/AIDS, tuberculosis, malaria)

Because subgroup analyses should be interpreted with caution, we applied the following criteria when interpreting the results: consideration of the direction of the point estimate per subgroup; overlap of the CIs of different subgroups; and statistical tests for differences between subgroups.

The available data did not allow subgroup analyses in relation to age (i.e. the individual studies included in our review did not stratify or report data in a way that allowed us to conduct such analyses). In Comparison 1, we assessed subgroups 1, 2 and 5, where data allowed. In Comparison 2, with only two studies, we could only apply subgroup 5; and in Comparison 3, we assessed subgroups 1, 3 and 5, where data allowed. More detail per comparison, as available data allowed, follows below ([Included studies](#)).

## Sensitivity analysis

Where data allowed, we performed sensitivity analyses on the four outcomes reported in the 'Summary of findings' tables, to assess the influence of study quality (using low risk of bias in selection bias, attrition bias, and other bias as markers) and study design (cluster trials versus individually randomised controlled trials) on the findings.

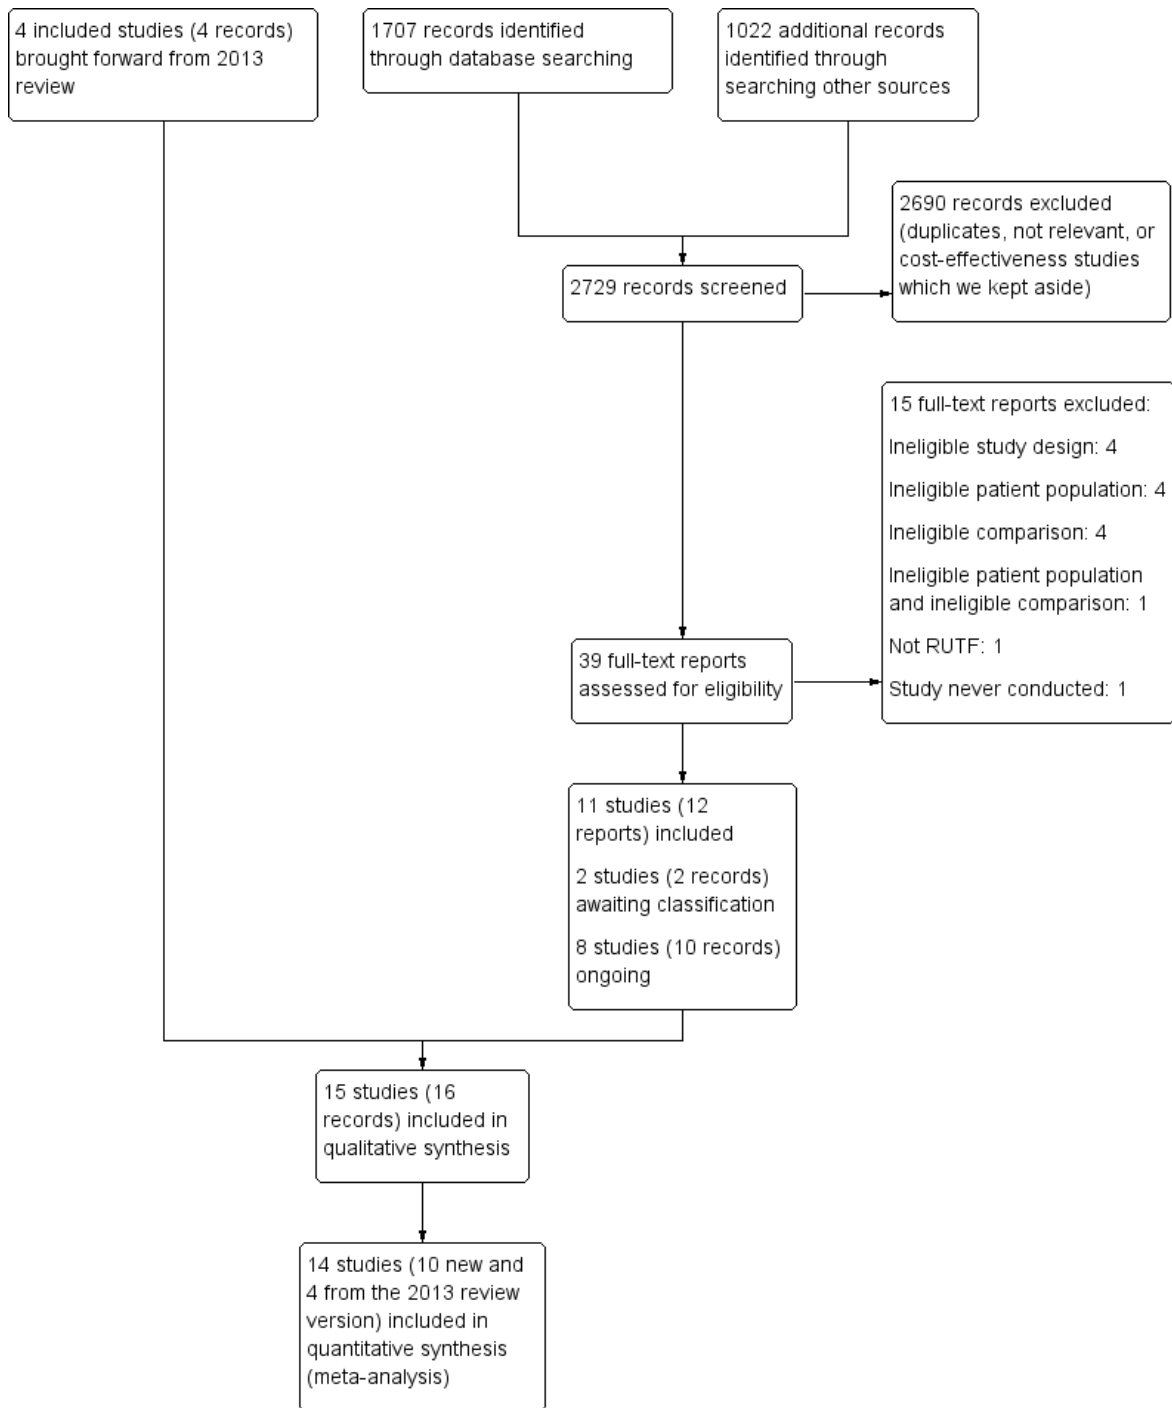

## RESULTS

### Description of studies

#### Results of the search

We recorded the results of the search and screening process in a PRISMA flow diagram; see [Figure 2](#). Briefly, we screened 2830 search results in 2013 ([Schoonees 2013](#)), and, for this update, an additional 2729 records (of which 526 were from the searches for cost-effectiveness studies) in 2017 and 2018. For this update, we scrutinised 39, new, full-text reports that we identified as potentially eligible for the effects (main) part of our review, and of these, selected 12 new reports (11 new studies) for inclusion ([Included studies](#)); categorised two new reports (two studies) as [Studies awaiting classification](#); identified 10 new reports (eight studies) of [Ongoing studies](#); and excluded 15 reports with reasons ([Excluded studies](#)). We used Google Translate to conduct a preliminary assessment of non-English abstracts, but did not need to obtain the full texts for any of these studies.

**Figure 2. PRISMA flow diagram of search for effectiveness section of the review**

## Included studies

This review includes 7976 children from a total of 15 studies: four from our 2013 review (Schoonees 2013) namely Ciliberto 2005, Manary 2004, Ndekha 2005 and Oakley 2010; and 11 that are new to this update (Bahwere 2014; Bhandari 2016; Hsieh 2015a; Hsieh 2015b; Irena 2015; Jadhav 2016; Jones 2015; Kerac 2009; Shewade 2013; Sigh 2018; Thapa 2017). Of these 15 studies, two were reported in the same article (Hsieh 2015a; Hsieh 2015b). We contacted the study authors and established that a detailed manuscript for Hsieh 2015b does not exist. In addition, we have included two reports of the same study as separate studies (Manary 2004; Ndekha 2005), as they involved different children, namely those with and without HIV. Four of the 15 included studies are cluster trials (Ciliberto 2005; Irena 2015; Manary 2004; Ndekha 2005). After calculating their respective effective sample sizes, the total number of children analysed in this review is 6630.

Our 2013 review, Schoonees 2013, included only studies conducted in Malawi (Ciliberto 2005; Manary 2004; Ndekha 2005; Oakley 2010). This review update includes an additional four studies from Malawi (Bahwere 2014; Hsieh 2015a; Hsieh 2015b; Kerac 2009), as well as four studies from India (Bhandari 2016; Jadhav 2016; Shewade 2013; Thapa 2017), and one study apiece from Zambia (Irena 2015), Kenya (Jones 2015), and Cambodia (Sigh 2018).

Overall, the duration of the intervention periods ranged from eight (Ciliberto 2005; Jadhav 2016; Oakley 2010; Sigh 2018; Thapa 2017) to 16 weeks (Bahwere 2014; Manary 2004). One trial, which only assessed acceptability, did not report the duration of the intervention (Hsieh 2015b), and two studies did not specify a maximum intervention duration (Irena 2015; Ndekha 2005). Only five studies followed up children after the intervention period (maximum of six months), and generally reported on a limited number of outcomes (Bhandari 2016; Ciliberto 2005; Jadhav 2016; Manary 2004; Ndekha 2005).

The section below provides a list of the included studies grouped according to the comparison assessed. Further details are given in the [Characteristics of included studies](#) tables, as well as in [Table 7](#) (Comparison 1), [Table 8](#) (Comparison 2) and [Table 9](#) (Comparison 3), which are based on the TIDieR table in [Hoffmann 2017](#).

### Comparison 1: standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

We included seven studies in this comparison (Bhandari 2016; Ciliberto 2005; Jadhav 2016; Manary 2004; Ndekha 2005; Shewade 2013; Thapa 2017).

1. [Bhandari 2016](#): an individually randomised, controlled trial, with 906 children aged 6 to 59 months in India. The study compared a standard peanut- and milk-based RUTF in two arms (one factory-produced and one produced in an institution kitchen) to caregiver-prepared, locally available foods (with energy-dense and nutrient-rich recipes).

2. [Ciliberto 2005](#): a stepped-wedge design (which we treated as a cluster, quasi-randomised trial) with children aged between 10 and 60 months in Malawi. Of the 1178 children that were randomised, 645 had SAM, with an effective sample size of 352. The study compared a standard peanut- and milk-based RUTF (factory-produced) to F-100 (start of rehabilitation as inpatients) and a caregiver-prepared flour porridge (maize and soy flour blend) at home.

3. [Jadhav 2016](#): an individually randomised, controlled trial with 321 children aged six months to five years in India. The study compared a standard peanut- and milk-based RUTF (produced in an institution kitchen) to an energy-dense and high protein diet from locally available foods (prepared in a hospital kitchen during admission, and by caregivers at home after discharge).

4. [Manary 2004](#): a cluster, quasi-randomised trial of 186 children (effective sample size = 182) older than 12 months of age who were not infected with HIV (HIV-uninfected) in Malawi. The study compared a standard peanut- and milk-based RUTF (factory-produced) to a caregiver-prepared flour porridge (maize and soy flour blend) at home.

5. [Ndekha 2005](#): a cluster, quasi-randomised trial of 65 children (effective sample size = 65) aged between 12 and 60 months who were infected with HIV (HIV-infected) in Malawi. The study compared a standard peanut- and milk-based RUTF (factory-produced) to a caregiver-prepared flour porridge (maize and soy flour blend) at home.

6. [Shewade 2013](#): an individually randomised, controlled trial with 26 children aged six months to five years in India. Each of the two groups received the same care (anthropometry, case management, feeding counselling, supplementary nutrition), but the experimental group also received a standard peanut- and milk-based RUTF produced in an institution kitchen.

7. [Thapa 2017](#): an individually randomised, controlled trial with 112 children aged six months to five years in India. The study compared a standard peanut- and milk-based RUTF (produced in an institution kitchen) to caregiver-prepared, precooked, locally available foods.

### Comparison 2: standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

We included two studies in this comparison (Manary 2004; Ndekha 2005).

Manary 2004 and Ndekha 2005: these are the same studies reported under Comparison 1, except for this Comparison, we used the RUTF and RUTF supplement groups in our analyses. The studies used similar RUTF products but in different portions.

### Comparison 3: standard RUTF versus RUTF using an alternative formulation

We included eight studies in this comparison (Bahwere 2014; Hsieh 2015a; Hsieh 2015b; Irena 2015; Jones 2015; Kerac 2009; Oakley 2010; Sigh 2018).

1. Bahwere 2014: an individually randomised, controlled trial of 600 children aged 6 to 59 months in Malawi. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing whey protein (factory-produced).

2. Hsieh 2015a: an individually randomised, controlled trial of 141 children aged between six months and five years in Malawi. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing high oleic fatty acids (factory-produced).

3. Hsieh 2015b: an individually randomised, controlled trial of 148 children aged between six months and five years in Malawi. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing high oleic fatty acids (factory-produced).

4. Irena 2015: a cluster-RCT of 1927 children (effective sample size = 881) across 12 clusters and aged between 6 and 60 months in Zambia. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing soy, maize and sorghum (factory-produced).

5. Jones 2015: an individually randomised, controlled trial of 61 children aged between 6 and 60 months in Kenya. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing flax seed oil (factory-produced).

6. Kerac 2009: an individually randomised, controlled trial with 795 children aged between 5 and 168 months in Malawi. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing pre- and probiotics (factory-produced).

7. Oakley 2010: an individually randomised, controlled trial of 1874 children aged between 6 and 59 months in Malawi. The study compared a standard milk-based RUTF (peanuts; factory-produced) to a RUTF containing only 10% milk and soy flour (factory-produced).

8. Sigh 2018: an individually randomised, controlled trial of 121 children aged between 6 to 59 months in Cambodia. The study compared a standard milk-based RUTF (cereal; factory-produced) to a RUTF containing locally available fish, mung

beans, rice, soybeans and rice flour (factory-produced).

Although Kerac 2009 was published in 2009, and we identified it in our earlier search, we did not include it in the original review (Schoonees 2013), because the abstract specified that the study included children aged 5 to 168 months, and we rejected the study during the titles and abstracts screening stage. For this review update, we obtained the full-text article for this study and determined that the majority of the children were in the six-month-to-five-year age group, and that the study authors had done a separate analysis for this group.

### Subgroup analyses

With the exception of one study (Hsieh 2015b), we were able to use data from our included studies to conduct four of our five, preplanned subgroup analyses (Schoonees 2011).

### Pre-trial hospital stabilisation versus no pre-trial hospitalisation

We conducted an analysis of the following subgroups for Comparisons 1 and 3 using data from 14 studies (Bahwere 2014; Bhandari 2016; Ciliberto 2005; Hsieh 2015a; Irena 2015; Jadhav 2016; Jones 2015; Kerac 2009; Manary 2004; Ndekha 2005; Oakley 2010; Shewade 2013; Sigh 2018; Thapa 2017).

1. All participants received in-hospital stabilisation before study enrolment

i) Comparison 1: three studies (Jadhav 2016; Manary 2004; Ndekha 2005)

ii) Comparison 3: one study (Kerac 2009)

2. Some of the participants received in-hospital stabilisation before study enrolment

i) Comparison 1: two studies (Bhandari 2016; Ciliberto 2005)

ii) Comparison 3: three studies (Bahwere 2014; Jones 2015; Sigh 2018)

3. No pre-trial inpatient stabilisation occurred

i) Comparison 1: two studies (Shewade 2013; Thapa 2017)

ii) Comparison 3: three studies (Hsieh 2015a; Irena 2015; Oakley 2010)

### Commercial (i.e. factory) versus non-commercial (i.e. institution kitchen) RUTF

We conducted an analysis of the following subgroups for Comparison 1 using data from six studies (Ciliberto 2005; Jadhav 2016; Manary 2004; Ndekha 2005; Shewade 2013; Thapa 2017).

1. Factory-produced RUTF

i) Comparison 1: three studies (Ciliberto 2005; Manary 2004; Ndekha 2005)

2. Local site-kitchen-produced RUTF

i) Comparison 1: three studies (Jadhav 2016; Shewade 2013; Thapa 2017)

### Different types of RUTF products (for example, corn and soy-based versus peanut-based RUTF)

We conducted an analysis of the following subgroups for Comparison 3 using data from seven studies (Bahwere 2014; Hsieh 2015a; Irena 2015; Jones 2015; Kerac 2009; Oakley 2010; Sigh 2018).

1. Studies where the control RUTF contained less or no milk powder: four studies (Bahwere 2014; Irena 2015; Oakley 2010; Sigh 2018)
2. Studies where the control RUTF contained specific fatty acids: two studies (Hsieh 2015a; Jones 2015)
3. Studies where the control RUTF contained pre- and probiotics: one study (Kerac 2009)

### Age of children: 6 to 12 months

The data from the included studies did not allow subgroup analyses of age.

### Children with or without comorbid disease (for example, HIV/AIDS, TB)

We conducted an analysis of the following subgroups for Comparisons 1 and 2 using the data from four studies (Bhandari 2016; Ciliberto 2005; Manary 2004; Ndekha 2005).

1. HIV-uninfected or untested children
  - i) Comparison 1: three studies (Bhandari 2016; Ciliberto 2005; Manary 2004)
  - ii) Comparison 2: one study (Manary 2004)
2. HIV-infected children
  - i) Comparison 1: one study (Ndekha 2005)
  - ii) Comparison 2: one study (Ndekha 2005)

### Sensitivity analysis

With the exception of one study (Hsieh 2015b), we were able to use data from our included studies to conduct our preplanned sensitivity analyses (Schoonees 2011).

### Study quality (using low risk of bias in selection bias, attrition bias, and other bias as marker of quality)

We conducted sensitivity analyses for Comparisons 1 and 3 using data from five studies (Bahwere 2014; Bhandari 2016; Jones 2015; Kerac 2009; Oakley 2010).

1. Comparison 1: one study (Bhandari 2016)
2. Comparison 3: four studies (Bahwere 2014; Jones 2015; Kerac 2009; Oakley 2010)

### Study design (cluster trials versus individually randomised, controlled trials)

We conducted sensitivity analyses for Comparisons 1 and 2 using data from 14 studies (Bahwere 2014; Bhandari 2016; Ciliberto 2005; Hsieh 2015a; Irena 2015; Jadhav 2016; Jones 2015; Kerac 2009; Manary 2004; Ndekha 2005; Oakley 2010; Shewade 2013; Sigh 2018; Thapa 2017).

1. individually randomised, controlled trials
  - i) Comparison 1: four studies (Bhandari 2016; Jadhav 2016; Shewade 2013; Thapa 2017)
  - ii) Comparison 3: six studies (Bahwere 2014; Hsieh 2015a; Jones 2015; Kerac 2009; Oakley 2010; Sigh 2018)
2. Cluster trials
  - i) Comparison 1: three studies (Ciliberto 2005; Manary 2004; Ndekha 2005)
  - ii) Comparison 3: one study (Irena 2015)

### Excluded studies

In total, we excluded 37 studies with reasons from this review; 22 studies from our 2013 review (Schoonees 2013), and a further 15 studies from this update (Ashraf 2017; Bahwere 2016; Bahwere 2017; Brown 2015; Choudhury 2018; CTRI/2013/02/003418; Dani 2017; Ige 2014; Malik 2016; Mallewa 2018; Manary 2013; Maust 2015; Nga 2013; Sato 2018; Wasnik 2012). The most common reasons for exclusion were that the study design was neither an RCT nor a quasi-randomised trial (n = 10); the intervention was not RUTF (n = 8); the participant population was not eligible (n = 8); and ineligible comparisons (n = 8). In addition, one study included an ineligible participant population and had an ineligible comparison, one study was about prevention and not rehabilitation, and one registered trial entry that appeared eligible was never conducted due to a lack of funding. See the [Characteristics of excluded studies](#) tables.

### Studies awaiting classification

In this update, we identified two studies that are awaiting classification (Huq 2013; Kaleem 2014).

Huq 2013 is a conference abstract of a study conducted in Bangladesh between 2009 and 2012. Detailed information about the interventions used (RUTF versus “rice-lentils based traditional-diets (khichuri and halwa)”) is not available. We emailed the study authors at least twice, requesting a copy of the full manuscript, but have yet to receive a response.

Kaleem 2014 is an individually randomised, controlled trial with 270 children aged 6 to 59 months in Pakistan, with three intervention groups: RUTF produced in a factory in France (n = 90), a “Homemade High Density Diet” (n = 90), and “Homemade High Density diet along with Micronutrient supplements” (n = 90). After careful consideration, we decided to place this study in the ‘awaiting assessment’ category, because the main results reported

for the two relevant groups in our Comparison 1 were identical and we feel this unusual scenario requires further clarification. We also found a discrepancy in the article for weight gain, where slightly different results were provided in the table compared to text, and an instance where the percentage events had not been calculated correctly. We are engaging with the study author in order to clarify these findings.

See the [Characteristics of studies awaiting classification](#) tables.

### Ongoing studies

In our 2013 review ([Schoonees 2013](#)), there were nine ongoing studies. Of these, four entries are now included in this review as [Bhandari 2016](#) (CTRI/2012/10/003054 and NCT01705769), [Irena 2015](#) (ISRCTN62376241) and [Shewade 2013](#) (CTRI/11/12/002259). One ongoing study entry (NCT01785680) in our 2013 review has been excluded with its published record, [Maust 2015](#), due to the study having had an ineligible study population and ineligible comparison. Regarding the other four ongoing studies from our 2013 review, we emailed the study authors to obtain available (published or unpublished) manuscripts ([NCT00131417](#); [NCT00941434](#); [NCT01144806](#); [NCT01634009](#)). The author for [NCT00131417](#) responded saying that the study had not yet been published, but an unpublished manuscript could be provided by September 2017. However, this has not yet been received after following up with the author again. Two studies have the same contact author, to whom we have sent repeated email requests for information, and who has not responded ([NCT00941434](#); [NCT01144806](#)). The author of [NCT01634009](#) informed us in 2017 that their “final analysis is ongoing” and that the researchers “may be able to share [the manuscript] after a couple of months”; however, we have not yet received it.

We identified six studies by searching trials registers in 2017 ([CTRI/2014/09/004958](#); [CTRI/2016/02/006656](#); [ISRCTN30393230](#); [ISRCTN50039021](#); [NCT01331044](#); [NCT03094247](#)). The authors of four studies informed us that their studies are still ongoing ([CTRI/2016/02/006656](#); [ISRCTN30393230](#); [ISRCTN50039021](#); [NCT03094247](#)). The author of [NCT01331044](#) informed us that

their manuscript is underway and will be available after peer review. We also contacted the author of [CTRI/2014/09/004958](#) in October 2017, but did not receive a response at the time of publication. In our 2018 search, we found two additional ongoing studies ([ISRCTN31143316](#); [NCT03407326](#)), for which the start dates in the trial registry entries are indicated as October 2017 and September 2018, respectively.

See [Characteristics of ongoing studies](#) tables.

### Funding sources and conflicts of interest

Of our 15 included studies, six were linked to funding or donations from industry ([Bahwere 2014](#); [Ciliberto 2005](#); [Jadhav 2016](#); [Manary 2004](#); [Ndekha 2005](#); [Thapa 2017](#)), one did not report the source of funding ([Hsieh 2015b](#)), and eight studies reported funding from non-industry sponsors ([Bhandari 2016](#); [Hsieh 2015a](#); [Irena 2015](#); [Jones 2015](#); [Kerac 2009](#); [Oakley 2010](#); [Shewade 2013](#); [Sigh 2018](#)).

One study declared a conflict of interest that was not industry-linked ([Bhandari 2016](#)). Two studies declared that one or more authors have a link to industry ([Bahwere 2014](#); [Irena 2015](#)), while two other studies reported that the authors have links to industry but declared no conflict of interest ([Jones 2015](#); [Kerac 2009](#)). Six studies declared no conflict of interest ([Ciliberto 2005](#); [Hsieh 2015a](#); [Jadhav 2016](#); [Oakley 2010](#); [Sigh 2018](#); [Thapa 2017](#)). The four remaining studies did not report on this matter ([Hsieh 2015b](#); [Manary 2004](#); [Ndekha 2005](#); [Shewade 2013](#)).

### Risk of bias in included studies

We have presented our judgements regarding the risk of bias in each of the included studies in the ‘Risk of bias’ tables beneath the [Characteristics of included studies](#) tables. We rated the overall risk of bias as high for six studies ([Ciliberto 2005](#); [Jadhav 2016](#); [Manary 2004](#); [Ndekha 2005](#); [Sigh 2018](#); [Thapa 2017](#)), unclear for three studies ([Hsieh 2015a](#); [Hsieh 2015b](#); [Irena 2015](#)), and low for six studies ([Bahwere 2014](#); [Bhandari 2016](#); [Jones 2015](#); [Kerac 2009](#); [Oakley 2010](#); [Shewade 2013](#)). [Figure 3](#) and [Figure 4](#) provide graphical summaries of the ‘Risk of bias’ assessments. For the four cluster studies, we have presented additional risk of bias information in [Table 10](#).

**Figure 3. 'Risk of bias' graph: review authors' judgements about each 'Risk of bias' item presented as percentages across all included studies**

**Figure 4. 'Risk of bias' summary: review authors' judgements about each 'Risk of bias' item for each included study**

## Allocation

Here, we refer to both the generation of the random allocation sequence and concealment of the allocation code.

We judged seven studies to be at low risk of selection bias (Bahwere 2014; Bhandari 2016; Jones 2015; Kerac 2009; Oakley 2010; Shewade 2013; Sigh 2018); three studies to be a high risk of selection bias as they were quasi-randomised (Ciliberto 2005; Manary 2004; Ndekha 2005); and five studies to be at unclear risk of bias as they either did not report the method of sequence generation (Hsieh 2015a; Hsieh 2015b; Thapa 2017) or did not report adequate allocation concealment (Irena 2015; Jadhav 2016).

## Blinding

### Blinding of participants and personnel (performance bias)

We judged 13 studies at low risk of performance bias because the participants across groups received the same amount of contact time with study personnel: it is not likely that children in one group performed better because they received more care (Bahwere 2014; Bhandari 2016; Ciliberto 2005; Hsieh 2015a; Irena 2015; Jadhav 2016; Jones 2015; Kerac 2009; Manary 2004; Ndekha 2005; Oakley 2010; Shewade 2013; Sigh 2018). Also, for the eight studies in which blinding was not done, we judged that the outcome measurements in children were not likely to be influenced by the lack of blinding of caregivers and study personnel (Bhandari 2016; Ciliberto 2005; Irena 2015; Jadhav 2016; Manary 2004; Ndekha 2005; Shewade 2013; Sigh 2018).

For the two studies where acceptability was the main focus, we judged one, Thapa 2017, at high risk of performance bias and the other, Hsieh 2015b, at unclear risk. In these studies, if caregivers knew what intervention their child was getting, we feel they could have influenced children to eat more or less RUTF, based on their own taste preferences or perception of the product. In addition, Thapa 2017 did not perform blinding, while Hsieh 2015b reported 'double-blinding' but did not explain how the blinding had been done.

### Blinding of outcome assessment (detection bias)

Seven studies reported that outcome assessors were unaware of the intervention that the child received (Bahwere 2014; Bhandari 2016; Hsieh 2015a; Hsieh 2015b; Jones 2015; Kerac 2009; Oakley 2010). We rated three of these studies, which did not explain how blinding was ensured, at unclear risk of detection bias (Hsieh 2015a; Hsieh 2015b; Oakley 2010). We considered the remaining four studies to be at low risk of detection bias.

We judged the eight remaining studies to be at unclear risk of detection bias (Ciliberto 2005; Irena 2015; Jadhav 2016; Manary

2004; Ndekha 2005; Shewade 2013; Sigh 2018; Thapa 2017), as the outcome assessors were not blinded and the majority of the primary and secondary outcomes were dependent on physical anthropometric measurements by outcome assessors.

### Incomplete outcome data

We rated four studies at low risk of attrition bias as they either did not have differential loss to follow-up in the two groups or they did not have substantial overall attrition (Bhandari 2016; Oakley 2010; Shewade 2013; Thapa 2017). Although Hsieh 2015a, had differential losses (8.6% versus 2.8%), we judged the study at low risk of attrition bias as the proportions were based on small numbers.

We considered four studies to have a high risk of attrition bias (Jadhav 2016; Manary 2004; Ndekha 2005; Sigh 2018). Jadhav 2016 and Sigh 2018 had substantial overall attrition, while Manary 2004 and Ndekha 2005 had differential loss to follow-up between two arms. Both Manary 2004 and Ndekha 2005 each had three arms: RUTF at a dose meeting total daily nutritional requirements, RUTF supplement in addition to the usual diet and flour porridge as control. In both studies, the RUTF supplement arm had more than double the percentage attrition compared to the other two arms.

We rated six studies at unclear risk of attrition bias; three because the study authors did not report how missing data for the ITT analyses were handled (Bahwere 2014; Irena 2015; Jones 2015); two because only a subgroup of the randomised participants was eligible for inclusion in our review and it is unclear whether randomisation was preserved in this smaller group (Ciliberto 2005; Kerac 2009); and one because it was not clear what were the sample size(s) for the different acceptability outcomes (Hsieh 2015b). We provided a summary of missing data in Table 6.

### Selective reporting

For each included trial, we searched for the protocol in the trials registries mentioned under Search methods for identification of studies, and contacted the primary study authors asking whether their studies had been registered. We judged five studies for which no protocol was available to be at unclear risk of reporting bias (Bahwere 2014; Ciliberto 2005; Hsieh 2015b; Manary 2004; Ndekha 2005). We judged another trial, Thapa 2017, which reported a trial registration number, to be at unclear risk of reporting bias also, because we could not find the registration entry on the Internet and the author did not respond to our communication. We judged a further eight studies at unclear risk of reporting bias because we found discrepancies between the prespecified outcomes (as per the protocol) and those that were addressed, and whether

this affected the validity of the outcome data is unclear (Bhandari 2016; Hsieh 2015a; Irena 2015; Jadhav 2016; Jones 2015; Oakley 2010; Shewade 2013; Sigh 2018).

We judged one trial, Kerac 2009, to be at low risk of reporting bias because all expected outcomes were prespecified and reported.

### Other potential sources of bias

We assessed the included studies for differences in baseline characteristics between comparison groups. We judged three studies to have a low risk of other bias as the baseline characteristics in the two groups appeared similar (Bhandari 2016; Jones 2015; Oakley 2010). We judged an additional four studies to be at low risk of other bias (Bahwere 2014; Hsieh 2015a; Manary 2004; Ndekha 2005); although there were differences in important baseline characteristics, these were likely due to chance.

We judged two individually randomised trials at unclear risk of other bias because they did not report on important baseline characteristics (Hsieh 2015b; Shewade 2013). We rated five studies at unclear risk of other bias; three studies - Irena 2015, Shewade 2013 and Sigh 2018 - used blocked randomisation that, in combination with a lack of blinding, could have posed a risk to selection bias (see section 8.15.1.3 in the *Cochrane Handbook for Systematic Reviews of Interventions* version 5.2 (Higgins 2017), and two studies did not report the baseline characteristics for the subgroups eligible to our review (Ciliberto 2005; Kerac 2009).

We rated two studies at high risk of other bias (Jadhav 2016; Thapa 2017). Jadhav 2016 reported baseline characteristics only for the children who remained in the study after two weeks (75.4%), and in Thapa 2017, there were substantial differences in the important baseline characteristics age and weight. It is likely that these influenced the results of all outcomes (except for acceptability).

In cluster trials, it is important to consider the unit of allocation to avoid potential bias. We investigated this for the four cluster trials (Ciliberto 2005; Irena 2015; Manary 2004; Ndekha 2005). While three of these studies did not adjust for clustering, one study adjusted for clustering in their multivariate analyses and provided the ICC used (Irena 2015). We also assessed recruitment bias, cluster baseline imbalances, loss of clusters, incorrect analysis and comparability with individually randomised trials for these four studies (Table 10). We judged two studies to have a low risk of recruitment bias because, although the children were recruited after the different clusters were allocated a specific intervention, an independent doctor discharged the children without knowing which discharge days or week matched which intervention (Manary 2004; Ndekha 2005). We judged two studies to have a high risk of recruitment bias because children were recruited after sites were assigned a specific intervention (Ciliberto 2005; Irena 2015). In terms of baseline imbalances, we judged three cluster trials to have an unclear risk of bias because no relevant information was provided to assess this particular aspect. We judged the fourth trial, Irena 2015, to have a low risk of baseline imbalances because the author per-

formed multivariate analyses to assess the effects of clusters and detected no interactions. All clusters in the four cluster trials were retained and, therefore, we judged all of them to be at low risk of bias for loss of clusters. For the incorrect analysis domain, we judged one study to be at low risk of bias because the study authors provided the ICC that we used to calculate the design effect (Irena 2015). However, for the other three studies, we had to estimate the ICC and are unsure how close our estimate is to the truth. In terms of comparability with individually randomised trials, we judged two studies to be at low risk of bias because for the four most important outcomes the findings of these studies are in line with that of the individually randomised trials (Ciliberto 2005; Irena 2015). We judged the other two studies to be at an unclear risk of bias for this aspect, as for some of the most important outcomes, the findings of the cluster trials were not in line with that of the individually randomised trials and it could possibly be because of aspects other than the study design (Manary 2004; Ndekha 2005).

### Effects of interventions

See: **Summary of findings for the main comparison** Standard ready-to-use therapeutic food (RUTF) provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach; **Summary of findings 2** Standard ready-to-use therapeutic food (RUTF) provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet; **Summary of findings 3** Standard ready-to-use therapeutic food (RUTF) versus RUTF using an alternative formulation

In this section, we report on all eligible outcomes addressed by the included studies for each of the pre-specified comparisons. We also provide a 'Summary of findings' table per comparison, each of which contains our three primary outcomes and an important secondary outcome, namely rate of weight gain (Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3).

Data did not allow us to analyse results by different age groups, and only a few studies (Kerac 2009; Manary 2004; Ndekha 2005), tested participants' HIV status, which limited the number of subgroup analyses we were able to do for this important comorbidity. No included study measured our secondary outcome 'cognitive function and development'. Nor did they specifically assess allergic reactions as an adverse outcome. Although three studies explicitly excluded children with known allergies (Bhandari 2016; Hsieh 2015a; Jones 2015), only one study reported that a child was lost to follow-up due to being diagnosed with an allergy (Bhandari 2016).

### Comparison 1: standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Seven studies with a total of 2261 children (effective sample size = 1964) evaluated the effects of RUTF meeting total daily

nutritional requirements versus alternative dietary approaches (Bhandari 2016; Ciliberto 2005; Jadhav 2016; Manary 2004; Ndekha 2005; Shewade 2013; Thapa 2017). Four studies randomised participants individually, and three studies assigned their participants in clusters (Ciliberto 2005; Manary 2004; Ndekha 2005). The three cluster trials were also quasi-randomised trials.

### Primary outcomes

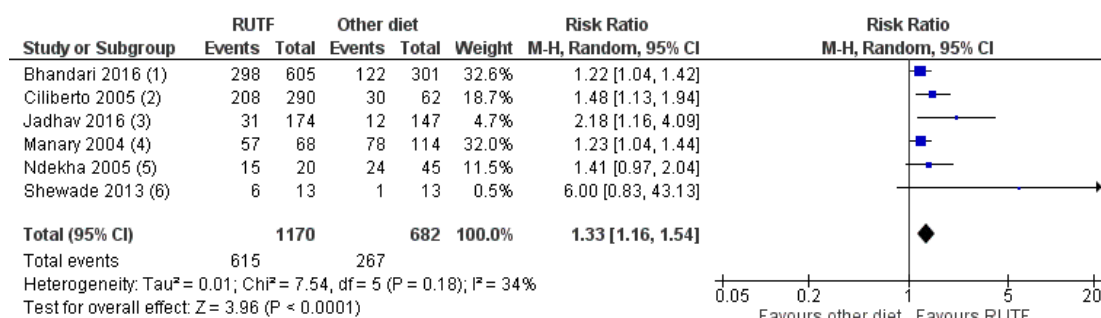

#### Recovery during intervention

Six studies measured and reported on recovery (Bhandari 2016; Ciliberto 2005; Jadhav 2016; Manary 2004; Ndekha 2005;

Shewade 2013). These studies measured recovery in different ways: achieving WHZ of  $-2$  or more and absence of oedema (Bhandari 2016); reaching a WHZ score more than  $-2$  and disappearance of oedema (Ciliberto 2005); WHZ more than  $-2$  (Jadhav 2016); having a WHZ score more than 0 (Manary 2004); reaching 100% weight for height (Ndekha 2005); and reaching 115% of baseline weight (Shewade 2013). Three studies were cluster trials (Ciliberto 2005; Manary 2004; Ndekha 2005), and we adjusted the results for clustering as described above (Unit of analysis issues).

A random-effects meta-analysis of these six studies showed that RUTF significantly improved recovery compared to the alternative diet (RR 1.33, 95% CI 1.16 to 1.54;  $n = 1852$ ; Analysis 1.1; Figure 5); there was no significant heterogeneity between the studies ( $\text{Chi}^2 = 7.54$ , degrees of freedom (df) = 5;  $P = 0.18$ ;  $I^2 = 34\%$ ).

**Figure 5. Forest plot of Comparison 1. Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, outcome: 1.1 recovery during intervention**

#### Footnotes

- (1) WHZ  $\geq -2$  and absence of oedema within 16 weeks of intervention.
- (2) WHZ  $> -2$  and without oedema, relapse or death within 8 weeks of intervention.
- (3) WHZ  $> -2$  within 8 weeks of intervention.
- (4) HIV-uninfected; WHZ  $> 0$  within 16 weeks of intervention.
- (5) HIV-infected; 100% weight for height within "some weeks" of intervention.
- (6) Reaching 115% of baseline weight within 12 weeks of intervention.

#### Subgroup and sensitivity analyses

There was also no heterogeneity between the findings in subgroup analysis based on pre-trial hospitalisation ( $\text{Chi}^2 = 2.42$ ,  $\text{df} = 2$ ;  $P = 0.30$ ;  $I^2 = 17.3\%$ ; Analysis 1.2).

The sensitivity analysis with Bhandari 2016, the only study at low risk of bias, showed a difference in favour of the RUTF group (RR 1.22, 95% CI 1.04 to 1.42;  $n = 906$ ; analysis not shown), which is in the same direction as the overall pooled effect estimate. A sensitivity analysis with individually randomised trials showed no difference between the RUTF and the alternative diet groups, although the CI was wide and is compatible with a potentially

substantial benefit (RR 1.73, 95% CI 0.92 to 3.26; 3 studies,  $n = 1253$ ;  $\text{Chi}^2 = 5.7$ ,  $\text{df} = 2$ ;  $P = 0.06$ ;  $I^2 = 65\%$ ; analysis not shown). However, in the analysis of cluster trials only, the pooled difference in effect favoured RUTF (RR 1.3, 95% CI 1.14 to 1.48; 3 studies,  $n = 599$ ;  $\text{Chi}^2 = 1.89$ ,  $\text{df} = 2$ ;  $P = 0.39$ ;  $I^2 = 0\%$ ; analysis not shown).

#### Recovery at follow-up

Two studies measured recovery at follow-up (Bhandari 2016; Jadhav 2016). Bhandari 2016 measured recovery (WHZ  $\geq -2$ ) at 16 weeks after the intervention ended, and Jadhav 2016 measured

recovery (WHZ > -2) six months after the intervention period. We found no significant difference between the RUTF and alternative diet groups (RR 1.10, 95% CI 0.83 to 1.46; 2 studies, n = 970; [Analysis 1.3](#)) and detected no heterogeneity between the studies ( $\text{Chi}^2 = 0.75$ ,  $\text{df} = 1$ ;  $P = 0.39$ ;  $I^2 = 0\%$ ).

### Relapse during intervention

Three studies defined relapse as admission to inpatient therapeutic care or recurrence of oedema or systematic infections during the study period ([Manary 2004](#); [Ciliberto 2005](#); [Ndekha 2005](#)). Specifically, [Manary 2004](#) reported results as “died or relapsed”. We contacted the study authors who sent us the separate data for “relapsed” and “died”. A fourth trial, [Bhandari 2016](#), reported hospitalisation during the treatment period, which we interpreted to be relapse.

A meta-analysis of these four studies showed no significant difference in relapse between the RUTF and alternative diet groups (RR 0.55, 95% CI 0.30 to 1.01; n = 1505; [Analysis 1.4](#)); however, there was significant heterogeneity between findings across studies ( $\text{Chi}^2 = 8.10$ ,  $\text{df} = 3$ ;  $P = 0.04$ ;  $I^2 = 63\%$ ).

One trial, [Jadhav 2016](#), did not set out to measure relapse, but large losses occurred during the intervention period. Because we applied the ITT principle, where we assumed that those who dropped out did not receive any treatment (RUTF or the control diet), and therefore experienced the event (relapsed), we have reported the losses of this study here for this outcome. In the RUTF group 98/174 (56.3%) dropped out of the trial, compared with 85/147 (57.8%) in the alternative diet group.

### Subgroup and sensitivity analyses

A subgroup analysis showed that when all children were hospitalised before the trial, the RUTF group was favoured (RR 0.34, 95% CI 0.17 to 0.66; n = 247; [Analysis 1.5](#)) and there was no heterogeneity between studies ( $\text{Chi}^2 = 0.17$ ,  $\text{df} = 1$ ;  $P = 0.68$ ;  $I^2 = 0\%$ ). In contrast, in the subgroup where some children were stabilised as inpatients prior to the trial, no significant difference was detected (RR 0.83, 95% CI 0.53 to 1.30; n = 1258; [Analysis 1.5](#)), and there was no significant heterogeneity ( $\text{Chi}^2 = 1.40$ ,  $\text{df} = 1$ ;  $P = 0.24$ ;  $I^2 = 28\%$ ). However, between subgroups, despite a slight overlap of CI, we detected significant heterogeneity ( $\text{Chi}^2 = 4.73$ ,  $\text{df} = 1$ ;  $P = 0.03$ ;  $I^2 = 78.9\%$ ).

There were no significant differences across subgroups in analyses of factory versus local site-produced RUTF ( $\text{Chi}^2 = 0.94$ ,  $\text{df} = 1$ ;  $P = 0.33$ ;  $I^2 = 0\%$ ; [Analysis 1.6](#)) and HIV status ( $\text{Chi}^2 = 1.25$ ,  $\text{df} = 1$ ;  $P = 0.26$ ;  $I^2 = 20.1\%$ ; [Analysis 1.7](#)).

A sensitivity analysis with [Bhandari 2016](#), the only individually randomised trial that was also at low risk of bias, showed no difference between the RUTF and alternative diet groups (RR 0.94, 95% CI 0.68 to 1.31; analysis not shown), which is in line with

the finding of the overall pooled effect estimate. However, a sensitivity analysis of cluster trials only detected a difference in favour of RUTF (RR 0.41, 95% CI 0.24 to 0.69; 3 studies, n = 599;  $\text{Chi}^2 = 0.99$ ,  $\text{df} = 2$ ;  $P = 0.61$ ;  $I^2 = 0\%$ ; analysis not shown).

### Relapse at follow-up

One trial, [Bhandari 2016](#), reported relapse during their “sustenance phase” (16 weeks after the end of intervention). They detected no significant difference between the RUTFs and alternative diet groups (RR 0.73, 95% CI 0.32 to 1.68; n = 838; see the illustrative forest plot in [Analysis 1.8](#)). Another trial, [Ciliberto 2005](#), measured relapse at 6 and 12 months after the intervention period, defined as WHZ less than -2 or oedema. However, they did not report results separately for SAM children. Two studies, [Manary 2004](#) and [Ndekha 2005](#), also reported this outcome six months after the intervention period; however, there were no separate results per intervention group (see Comparison 2 for the findings across all three study groups).

### Mortality during intervention

Four studies measured mortality ([Bhandari 2016](#); [Ciliberto 2005](#); [Manary 2004](#); [Ndekha 2005](#)). We detected no difference in mortality between the RUTF and alternative diet groups, with a wide CI around the point estimate (RR 1.05, 95% CI 0.51 to 2.16; 4 studies; n = 1505; [Analysis 1.9](#)), and no significant heterogeneity between the studies ( $\text{Chi}^2 = 2.20$ ;  $\text{df} = 3$ ;  $P = 0.53$ ;  $I^2 = 0\%$ ). Another trial, [Jadhav 2016](#), set out to measure mortality; however, they did not report any results. We contacted the study author but did not receive a response.

### Subgroup and sensitivity analyses

There was no overall difference between subgroups based on pre-trial hospitalisation ( $\text{Chi}^2 = 0.35$ ,  $\text{df} = 1$ ;  $P = 0.56$ ;  $I^2 = 0\%$ ; [Analysis 1.10](#)).

The sensitivity analysis with [Bhandari 2016](#), the only individually randomised study that was also at low risk of bias, showed no difference between the RUTF and alternative diet groups (RR 3.49, 95% CI 0.18 to 67.32; analysis not shown). Similarly, a sensitivity analysis with cluster trials only also detected no difference between the groups (RR 0.97, 95% CI 0.46 to 2.05; 3 studies, n = 599;  $\text{Chi}^2 = 1.5$ ,  $\text{df} = 2$ ;  $P = 0.47$ ;  $I^2 = 0\%$ ; analysis not shown).

### Secondary outcomes

#### Rate of weight gain during intervention

All seven studies included in this comparison measured weight gain, four of which we could pool in a meta-analysis.

Three studies, [Manary 2004](#), [Ciliberto 2005](#) and [Ndekha 2005](#), reported weight gain measured during the first four weeks of the intervention period (we obtained data on weight gain from the contact author of [Manary 2004](#)). One trial, [Bhandari 2016](#), measured the same outcome between baseline and recovery or 16 weeks after enrolment, whichever was earlier. We found a significant difference in favour of the RUTF group (MD 1.12 g/kg/day, 95% CI 0.27 to 1.96; 4 studies; n = 1450; [Analysis 1.11](#)), but detected significant heterogeneity between the studies ( $\text{Chi}^2 = 7.40$ ;  $\text{df} = 3$ ;  $\text{P} = 0.06$ ;  $\text{I}^2 = 59\%$ ).

One trial, [Jadhav 2016](#), reported weight gain over eight weeks of intervention of 3.45 g/kg/day in the RUTF group and 2.38 g/kg/day in the alternative diet group; however, the corresponding SD were not reported and therefore we could not include the results in the meta-analysis above.

Another trial, [Shewade 2013](#), reported a mean weight gain of 21.5 g/kg/week (range = 3.5 to 63; n = 13) for the RUTF group and 7.89 g/kg/week (range = 0.2 to 23.8; n = 13) for the alternative diet groups. From the linear regression results reported by the study authors, the RUTF group resulted in an average additional weight gain of 13 g/kg/week/child (95% CI 2 to 23), which was statistically significant.

The final trial, [Thapa 2017](#), reported that the RUTF group had significantly higher weight gain (23 g/day) in comparison with the alternative diet group (14 g/day); however, these results should be viewed with caution as the baseline weight per group was highly unbalanced and the time point at which this result was taken is unclear. We could not add these results to the meta-analysis above because they did not report the results in g/kg/day and the study author did not respond to our communication.

### *Subgroup and sensitivity analyses*

We attempted to determine the potential source of heterogeneity in [Analysis 1.11](#), by conducting a subgroup analysis of pre-trial hospitalisation ([Analysis 1.12](#)). We found results in favour of the RUTF group for studies where all children were stabilised in hospital (MD 1.57 g/kg/day, 95% CI 0.32 to 2.82; 4 studies, n = 243), but there was significant heterogeneity between the studies in this subgroup ( $\text{Chi}^2 = 2.21$ ;  $\text{df} = 1$ ;  $\text{P} = 0.14$ ;  $\text{I}^2 = 55\%$ ). We also found a statistically significant difference in favour of RUTF for the subgroup where only some children were stabilised in hospital pre-trial (MD 0.65 g/kg/day, 95% CI 0.16 to 1.14; n = 1207), and detected no significant heterogeneity between these studies ( $\text{Chi}^2 = 0.00$ ;  $\text{df} = 1$ ;  $\text{P} = 0.97$ ;  $\text{I}^2 = 0\%$ ). We found no significant heterogeneity between the subgroups ( $\text{Chi}^2 = 1.80$ ;  $\text{df} = 1$ ;  $\text{P} = 0.18$ ;  $\text{I}^2 = 44.5\%$ ).

Subgroup analyses of factory versus local site-produced RUTF ( $\text{Chi}^2 = 0.07$ ,  $\text{df} = 1$ ;  $\text{P} = 0.79$ ;  $\text{I}^2 = 0\%$ ; [Analysis 1.13](#)) and HIV status ( $\text{Chi}^2 = 0.19$ ,  $\text{df} = 1$ ;  $\text{P} = 0.67$ ;  $\text{I}^2 = 0\%$ ; [Analysis 1.14](#)) also showed no differences across subgroups (4 studies, n = 1450).

The sensitivity analysis with [Bhandari 2016](#), the only individually randomised trial that was also at low risk of bias, showed a difference favouring the RUTF group (MD 0.65 g/kg/day, 95% CI 0.15 to 1.15; analysis not shown), which is in line with the overall pooled effect estimate. Similarly, a sensitivity analysis with the cluster trials only detected a significant difference in favour of RUTF (MD 1.47 g/kg/day, 95% CI 0.49 to 2.45; 3 studies, n = 595;  $\text{Chi}^2 = 2.92$ ,  $\text{df} = 2$ ;  $\text{P} = 0.23$ ;  $\text{I}^2 = 32\%$ ; analysis not shown).

### **Time to recovery (days) among children who recovered**

Four studies measured and reported on time to recovery ([Bhandari 2016](#); [Ciliberto 2005](#); [Manary 2004](#); [Ndekha 2005](#)).

One trial, [Bhandari 2016](#), reported mean duration to treatment in weeks, which we converted to days. Another trial, [Manary 2004](#), which included HIV-uninfected children, also reported time to recovery but results were displayed only in a graph from which we could not obtain accurate information for further analysis. We contacted the study authors, who provided us with the necessary information to add these data to the meta-analysis. We pooled the results from these two studies and detected a significant difference in favour of the RUTF group (MD -7.61 days, 95% CI -12.84 to -2.37; n = 556; [Analysis 1.15](#)), with no significant heterogeneity between the two studies ( $\text{Chi}^2 = 0.03$ ;  $\text{df} = 3$ ;  $\text{P} = 0.87$ ;  $\text{I}^2 = 0\%$ ). One trial, [Ciliberto 2005](#), performed a time-to-event analysis to compare the rates of reaching a WHZ more than -2 over eight weeks, but did not report the results separately for children with SAM.

Another trial, [Ndekha 2005](#), measured time to recovery and reported results in median days. HIV-infected children in the RUTF group (n = 20) recovered within a median of 71 days (interquartile range 42 to 125) compared to 85 days (interquartile range 46 to 239) in the alternative diet group (n = 45). The study authors did not report a P value or significance for the difference in time to recovery between these two groups.

### **Anthropometrical status at the end of the intervention period and beyond**

#### *Weight-for-height z score (WHZ) during intervention*

Two studies reported on this outcome ([Ciliberto 2005](#); [Shewade 2013](#)). [Ciliberto 2005](#) reported WHZ in end values and did not find a significant difference between the RUTF and alternative diet groups (MD 0.00, 95% CI -0.28 to 0.28; n = 352; [Analysis 1.16](#)). [Shewade 2013](#) measured WHZ and used the data in linear regression but did not report change or end values per group.

### *Weight-for-height z score (WHZ) at follow-up*

Two studies reported on this outcome (Bhandari 2016; Manary 2004). Bhandari 2016 reported this outcome as change at follow-up 16 weeks after the end of the intervention period. In Manary 2004, HIV-uninfected children who recovered and were discharged from the study were followed up for six months; we obtained end value data from the contact author. We pooled the results of these two studies in a meta-analysis and found no significant difference in WHZ between the RUTF and alternative diet groups (MD 0.06, 95% -0.04 to 0.16; n = 937; Analysis 1.17) with no significant heterogeneity between the studies ( $\text{Chi}^2 = 0.43$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.51$ ;  $\text{I}^2 = 0\%$ ).

### *Length/height gain during intervention*

Four studies measured this outcome (Ciliberto 2005; Manary 2004; Ndekha 2005; Thapa 2017). Ciliberto 2005 and Ndekha 2005 measured length/height gain during the intervention period. We pooled the data from these studies in a meta-analysis and detected no significant difference between the RUTF and alternative diet groups (MD 0.12 mm/day, 95% 0.00 to 0.24; n = 417; Analysis 1.18), with no significant heterogeneity between the studies ( $\text{Chi}^2 = 1.58$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.21$ ;  $\text{I}^2 = 37\%$ ). Thapa 2017 reported height in centimetres at the end of the eight-week intervention period but provided no SD of change. Therefore, we were unable to include this result in the above meta-analysis. Manary 2004 also reported height gain (mm/day), but provided results in a bar chart format and not as numerical data.

### *Height-for-age z score (HAZ) at follow-up*

One trial, Bhandari 2016, reported HAZ score at 16 weeks after the end of the intervention period. There was no significant difference between the RUTF and alternative diet groups (MD -0.02, 95% -0.09 to 0.05; n = 838; see the illustrative forest plot in Analysis 1.19).

### *Mid-upper arm circumference (MUAC) gain during intervention*

Three studies measured MUAC gain during the first four weeks of the intervention period (Manary 2004; Ciliberto 2005; Ndekha 2005). Manary 2004 reported data only in graph form and we obtained the actual values from the contact author. We pooled these three studies in a meta-analysis and found that children in the RUTF group had higher MUAC gain compared to those in the alternative diet group (MD 0.13 mm/day, 95% CI 0.04 to

0.21; n = 570; Analysis 1.20), with no significant heterogeneity between studies ( $\text{Chi}^2 = 2.30$ ;  $\text{df} = 2$ ;  $\text{P value} = 0.32$ ;  $\text{I}^2 = 13\%$ ). One trial, Thapa 2017, reported MUAC at the end of the eight weeks of intervention, but there were no SD of change so we could not include this study in the meta-analysis.

### *Mid-upper arm circumference (MUAC) gain at follow-up*

One trial, Bhandari 2016, reported the MUAC gain (in cm) during their sustenance phase (16 weeks after the end of the intervention): there was no significant difference between the RUTF and the alternative diet groups (MD -0.04 cm, 95% CI -1.04 to 0.96, n = 838; see the illustrative forest plot in Analysis 1.21).

### **Cognitive function and development**

No study presented data for this outcome.

### **Adverse outcomes**

Six studies reported on adverse outcomes (Bhandari 2016; Ciliberto 2005; Jadhav 2016; Manary 2004; Ndekha 2005; Thapa 2017).

One trial, Bhandari 2016 reported the number of children having diarrhoea during the treatment phase; there was no significant difference in the frequency of diarrhoea between the RUTF and the alternative diet groups (RR 1.00, 95% CI 0.83 to 1.20, n = 727; see the illustrative forest plot in Analysis 1.22).

Another trial, Ciliberto 2005, measured the numbers of days of diarrhoea per group during the first two weeks of the treatment period and found that children who received RUTF had a similar frequency of diarrhoea as those on the alternative diet (MD -0.60 days, 95% CI -1.30 to 0.10; n = 352; see the illustrative forest plot in Analysis 1.23).

A third trial, Jadhav 2016, set out to measure infectious episodes; however, no results were reported. We contacted the study author but did not receive a response.

Two studies, Ndekha 2005 and Manary 2004, measured the "prevalence of diarrhoea": days of diarrhoea divided by the "total days" during the first two weeks of the treatment period. In HIV-infected children (Ndekha 2005), the RUTF group (n = 20) had diarrhoea on 19 out of the 304 evaluated days compared to 57 out of 687 evaluated days for children (n = 45) in the alternative diet group. In HIV-uninfected children (Manary 2004), those in the RUTF group (n = 67) had diarrhoea on 74/1959 days (3.8%) compared to 74/3228 days (2.3%) in the alternative diet group (n = 114). This outcome refers to the number of days children had diarrhoea, and not the number of children who had diarrhoea. Therefore, we could not adjust the data for clustering and thus could not calculate the treatment effect from these two studies.

One trial, Thapa 2017, reported that no "adverse effects" were documented in the experimental group, while three (of 56) children

in the control group had acute diarrhoea, which resolved without the administration of antibiotics.

### Acceptability

One trial, [Thapa 2017](#), measured acceptance of the intervention and found that RUTF was more acceptable than the alternative diet (RR 1.37, 95% CI 1.13 to 1.66; n = 112; see the illustrative forest plot in [Analysis 1.24](#)).

Although not explicitly measured as acceptability, another trial, [Shewade 2013](#), measured compliance in the experimental group by asking mothers to return empty RUTF packets on a weekly basis. The average weekly consumption of RUTF was reported as 23.4% of that expected, with the range between 1.7% and 48.4%.

### Comparison 2: standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Two quasi-randomised, cluster trials that used systematic sequence-generation methods had the following three arms:

1. standard RUTF meeting total daily nutritional requirements;
2. a similar RUTF given supplementary to children's usual diet; and
3. porridge made by caregivers from a maize and soy flour blend as control ([Manary 2004](#); [Ndekha 2005](#)).

Below, we compare the standard RUTF (total daily requirements) with RUTF as a supplement (213 children in total; effective sample size = 210). [Manary 2004](#) included only HIV-uninfected children while [Ndekha 2005](#) only assessed HIV-infected children.

### Primary outcomes

#### Recovery during intervention

Both studies in this comparison measured recovery, defined as WHZ more than 0 ([Manary 2004](#)), and 100% weight for height ([Ndekha 2005](#)). Children who received standard RUTF were more likely to recover than those who received it as a supplement (RR 1.41, 95% CI 1.19 to 1.68; n = 210; [Analysis 2.1](#)). There was no significant heterogeneity between the studies ( $\text{Chi}^2 = 0.37$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.54$ ;  $\text{I}^2 = 0\%$ ).

#### Subgroup analysis

Recovery was in favour of standard RUTF in both the HIV-uninfected (RR 1.38, 95% CI 1.15 to 1.67; 1 trial, n = 162; [Manary 2004](#)) and HIV-infected (RR 1.62, 95% CI 1.01 to 2.59; 1 trial, n = 48; [Ndekha 2005](#)) subgroups.

#### Relapse during intervention

Both [Manary 2004](#) and [Ndekha 2005](#) measured relapse (admission to hospital) during the intervention period. Pooled results indicated that standard RUTF significantly reduced relapse compared to the supplementary group (RR 0.11, 95% CI 0.01 to 0.85; n = 210; [Analysis 2.2](#)), with no significant heterogeneity between the studies ( $\text{Chi}^2 = 0.30$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.58$ ;  $\text{I}^2 = 0\%$ ).

#### Subgroup analysis

When we separated the results into subgroups based on HIV status, there was no significant difference in relapse detected between the two groups in both HIV-uninfected (RR 0.07, 95% CI 0.00 to 1.10; 1 trial, n = 162; [Manary 2004](#)), and HIV-infected (RR 0.20, 95% CI 0.01 to 3.62; 1 trial, n = 48; [Ndekha 2005](#)), children.

#### Mortality during intervention

When comparing the standard RUTF with the RUTF supplement group ([Manary 2004](#); [Ndekha 2005](#)), we detected no significant difference in mortality (RR 1.36, 95% CI 0.46 to 4.04; n = 210; [Analysis 2.3](#)), and there was no significant heterogeneity between the studies ( $\text{Chi}^2 = 0.36$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.55$ ;  $\text{I}^2 = 0\%$ ).

#### Subgroup analysis

We detected no significant difference in mortality when assessing results for the subgroups of HIV-uninfected (RR 2.07, 95% CI 0.36 to 12.07; 1 trial, n = 162; [Manary 2004](#)) and HIV-infected (RR 1.05, 95% CI 0.26 to 4.18; 1 trial, n = 48; [Ndekha 2005](#)) children.

### Secondary outcomes

#### Rate of weight gain during intervention

Both studies in this comparison measured weight gain during the first four weeks of the intervention period ([Manary 2004](#); [Ndekha 2005](#)). We pooled the results in a meta-analysis and found no significant difference in weight gain between the standard RUTF and the RUTF supplement group (MD 1.21 g/kg/day, 95% CI -0.74 to 3.16; 2 studies, n = 206; [Analysis 2.4](#)), with substantial heterogeneity between the studies ( $\text{Chi}^2 = 4.26$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.04$ ;  $\text{I}^2 = 76\%$ ).

### *Subgroup analysis*

Subgroup analysis with respect to HIV status found that HIV-uninfected children in the standard RUTF group gained significantly more weight compared to the RUTF supplement group (MD 2.10 g/kg/day, 95% CI 1.12 to 3.08; 1 trial, n = 158; [Manary 2004](#)); however, for HIV-infected children, there was no significant difference in weight gain between the two groups (MD 0.10 g/kg/day, 95% CI -1.53 to 1.73; 1 trial, n = 48; [Ndekha 2005](#)).

### **Time to recovery (days) during intervention**

Among HIV-uninfected children who recovered, those who received standard RUTF recovered more rapidly than children in the RUTF supplement group (MD -10.0 days, 95% CI -19.13 to -0.87; 1 trial, n = 116; see the illustrative forest plot in [Analysis 2.5](#); [Manary 2004](#)). Among all HIV-infected participants in [Ndekha 2005](#), those in the standard RUTF group recovered within a median of 71 days (interquartile range 42 to 125) compared to the RUTF supplement group, which required a median of 115 days (interquartile range 59 to 195; P value not reported in the article).

### **Anthropometrical status**

#### *Weight-for-height z scores (WHZ) at follow-up*

One trial, [Manary 2004](#), followed up HIV-uninfected children who recovered and were discharged from the study for six months. We obtained the results (as end values) from the study author, which indicated that there was no significant difference in WHZ between children who received standard RUTF and those who received a similar RUTF as a supplement (MD 0.10, 95% CI -0.36 to 0.56; n = 72; [Analysis 2.6](#)).

#### *Length/height gain during intervention*

HIV-uninfected children receiving standard RUTF gained more height than the children who received the RUTF as a supplement (MD 0.20 mm/day, 95% CI 0.00 to 0.40; 1 trial, n = 48; see the illustrative forest plot in [Analysis 2.7](#); [Ndekha 2005](#)).

[Manary 2004](#) also reported height gain (mm/day), but provided results in a bar chart format and not as numerical data.

#### *Mid-upper arm circumference (MUAC) gain during intervention*

We detected no significant difference in MUAC gain during the first four weeks of the intervention period between the two intervention groups (MD 0.11 mm/day, 95% CI -0.01 to 0.22; 2

studies, n = 173; [Analysis 2.8](#); [Manary 2004](#); [Ndekha 2005](#)), and no significant heterogeneity between the studies ( $\text{Chi}^2 = 1.35$ ;  $\text{df} = 1$ ;  $\text{P value} = 0.25$ ;  $\text{I}^2 = 26\%$ ). When we separated the results by HIV status, in HIV-uninfected children, the standard RUTF group had significantly higher MUAC gain than those in the RUTF supplement group (MD 0.15 mm/day, 95% CI 0.03 to 0.27; 1 trial, n = 125; [Manary 2004](#)), while in HIV-infected children, there was no significant difference between the intervention groups (MD 0.03 mm/day, 95% CI -0.14 to 0.20; 1 study n = 48; [Ndekha 2005](#)).

### **Cognitive function and development**

No study presented data for this outcome.

### **Adverse outcomes**

Both studies reported on adverse outcomes ([Manary 2004](#); [Ndekha 2005](#)).

In HIV-uninfected children ([Manary 2004](#)), the standard RUTF group (n = 68) had diarrhoea on 74/1959 days (3.8%) compared to 181/2565 days (7.1%) in the RUTF supplement group (n = 94). This outcome refers to the number of days children had diarrhoea, and not the number of children who had diarrhoea. Therefore, we could not adjust the data for clustering and thus could not calculate the treatment effect from these two studies.

In HIV-infected children, [Ndekha 2005](#) measured the “prevalence of diarrhoea”: days of diarrhoea divided by the “total days” during the first two weeks of the intervention period. Study authors reported that children in the standard RUTF group had diarrhoea on 19 of the 304 evaluation days while those in the RUTF supplement group had diarrhoea on 38 of the 432 days. We were unsure about the meaning of “total days” as the figures did not correspond to the total number of days of each participant for each group. Since the corresponding numbers of participants were not reported, we could not calculate a treatment effect.

### **Acceptability of RUTF**

No study provided data on this outcome.

### **Comparison 3: standard RUTF versus RUTF using an alternative formulation**

Seven studies with a total of 5502 children (effective sample size = 4456) evaluated the effects of RUTF versus other types of RUTF ([Bahwere 2014](#); [Hsieh 2015a](#); [Irena 2015](#); [Jones 2015](#); [Kerac 2009](#); [Oakley 2010](#); [Sigh 2018](#)). A further study that randomised 148 children also addressed this comparison but only measured acceptability ([Hsieh 2015b](#)). All but one study randomised participants individually; [Irena 2015](#) was a cluster-randomised trial.

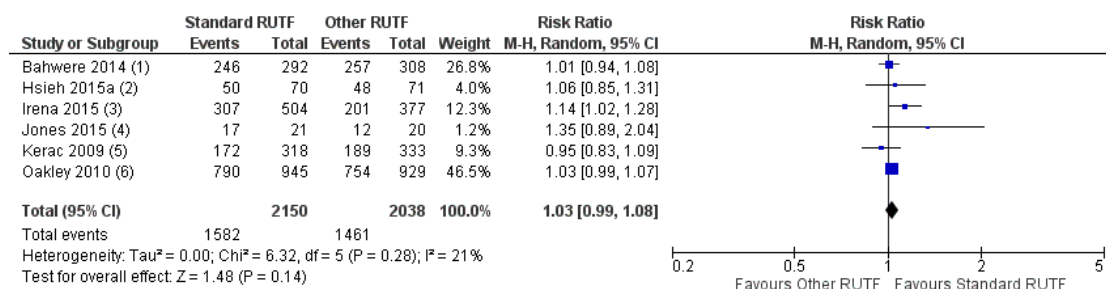

## Primary outcomes

### Recovery during intervention

Six studies measured recovery in different ways: Bahwere 2014 as weight gain of 15% or more of baseline weight; Irena 2015 as weight gain of 18% or more of baseline weight together with the absence of complications and MUAC more than 110 mm; Hsieh 2015a as MUAC more than 12.4 cm without oedema; Kerac 2009 as WHZ of 80% or more for two consecutive visits; and Oakley 2010 as having a WHZ more than -2 and no oedema. Jones

2015 also measured recovery but did not report the results in the manuscript. We obtained the data and definition from the study authors: MUAC more than 11.5 cm or WHZ more than -3 or no oedema (depending on admission criteria) on two consecutive visits. We pooled the data from these six studies in a meta-analysis and found no significant difference in recovery between the two groups who received different formulations of RUTF (RR 1.03, 95% CI 0.99 to 1.08; n = 4188; Analysis 3.1; Figure 6). We detected no significant heterogeneity between these studies ( $\text{Chi}^2 = 6.32$ ;  $\text{df} = 5$ ;  $P$  value = 0.28;  $I^2 = 21\%$ ).

**Figure 6. Forest plot of Comparison 3. Standard RUTF versus RUTF using an alternative formulation, outcome: 3.1 recovery during intervention**

#### Footnotes

(1) Weight gain  $\geq 15\%$ , absence of medical complications and oedema, MUAC  $> 11.0$  cm within 16 weeks of intervention.

(2) MUAC  $> 12.4$  cm without oedema within 12 weeks.

(3) Weight gain  $\geq 18\%$ , absence of medical complications and oedema, MUAC  $> 11.0$  cm; no maximum intervention period.

(4) MUAC  $> 11.5$  cm or WHZ  $> -3$  or no oedema (depending on admission criteria) on two consecutive visits within 12 weeks of intervention.

(5) WHZ  $\geq 80\%$  for two consecutive visits within 10 weeks of intervention.

(6) WHZ  $> -2$  and no edema within 8 weeks of intervention.

### Subgroup and sensitivity analysis

When exploring subgroups based on pre-trial hospitalisation, we found no significant difference in recovery during the intervention between the different types of RUTE, in each of the subgroups. Overall, there was no difference between the subgroups ( $\text{Chi}^2 = 1.94$ ,  $\text{df} = 2$ ;  $P = 0.38$ ;  $I^2 = 0\%$ ; Analysis 3.2).

A sensitivity analysis of studies at low risk of bias (Bahwere 2014; Jones 2015; Kerac 2009; Oakley 2010), only showed no difference between the different types of RUTF formulations (RR 1.02, 95% CI 0.99 to 1.06; n = 3166;  $\text{Chi}^2 = 3.03$ ,  $\text{df} = 3$ ;  $P = 0.39$ ;  $I^2 = 1\%$ ; 4 studies; analysis not shown), which is in line with the overall pooled effect estimate. A sensitivity analysis with individually randomised studies (all studies for this outcome except for Irena 2015), also showed no difference between the groups (RR 1.02, 95% CI 0.99 to 1.06; 5 studies, n = 3307;  $\text{Chi}^2 = 3.10$ ,  $\text{df} = 4$ ;  $P = 0.54$ ;  $I^2 =$

0%; analysis not shown) while a sensitivity analysis of the cluster-randomised trial (Irena 2015), showed a difference in favour of the standard RUTF (RR 1.14, 95% CI 1.02 to 1.28; 1 trial, n = 881; analysis not shown).

### Relapse during intervention

Six studies defined relapse in different ways: Bahwere 2014 and Irena 2015 defined relapse as being absent for three consecutive visits and could not be traced; Hsieh 2015a and Jones 2015 as loss to follow-up after 12 weeks; Kerac 2009 as defaulters, readmissions to inpatient care and lost to follow-up; and Oakley 2010 as remaining wasted after two consecutive visits. We pooled these six studies in a meta-analysis and found that the standard RUTF significantly reduced relapse (RR 0.84, 95% CI 0.72 to 0.98; n = 4188; Analysis 3.3), with no significant heterogeneity between

these studies ( $\text{Chi}^2 = 3.79$ ;  $\text{df} = 5$ ;  $\text{P value} = 0.58$ ;  $\text{I}^2 = 0\%$ ).

### Subgroup and sensitivity analysis

When exploring subgroups based on pre-trial hospitalisation, we found no significant difference in relapse during the intervention between the different types of RUTF, in each of the subgroups. Overall, there was no difference between the subgroups ( $\text{Chi}^2 = 0.62$ ,  $\text{df} = 2$ ;  $\text{P} = 0.73$ ;  $\text{I}^2 = 0\%$ ; [Analysis 3.4](#)).

A sensitivity analysis of studies at low risk of bias ([Bahwere 2014](#); [Jones 2015](#); [Kerac 2009](#); [Oakley 2010](#)), only showed no difference between the different types of RUTF formulations (RR 0.86, 95% CI 0.69 to 1.07;  $n = 3166$ ;  $\text{Chi}^2 = 1.99$ ,  $\text{df} = 3$ ;  $\text{P} = 0.57$ ;  $\text{I}^2 = 0\%$ , 4 studies; analysis not shown), which is not in line with the overall pooled effect estimate. A sensitivity analysis with individually randomised studies (all studies for this outcome except [Irena 2015](#)), also showed no difference between the groups (RR 0.88, 95% CI 0.71 to 1.09; 5 studies,  $n = 3307$ ;  $\text{Chi}^2 = 3.52$ ,  $\text{df} = 4$ ;  $\text{P} = 0.48$ ;  $\text{I}^2 = 0\%$ ; analysis not shown), while the cluster-randomised trial, [Irena 2015](#), had a similar result to the overall pooled effect estimate (RR 0.81, 95% CI 0.66 to 1.0; 1 trial,  $n = 881$ ; analysis not shown).

### Mortality during intervention

We did not find a significant difference in the number of deaths between the standard and the other RUTFs (RR 1.00, 95% CI 0.80 to 1.24; 7 studies,  $n = 4309$ ; [Analysis 3.5](#); [Bahwere 2014](#); [Hsieh 2015a](#); [Irena 2015](#); [Jones 2015](#); [Kerac 2009](#); [Oakley 2010](#); [Sigh 2018](#)), and detected no significant heterogeneity between studies ( $\text{Chi}^2 = 6.60$ ;  $\text{df} = 6$ ;  $\text{P value} = 0.36$ ;  $\text{I}^2 = 9\%$ ).

### Subgroup and sensitivity analysis

When exploring subgroups based on pre-trial hospitalisation, we found no significant difference in mortality during the intervention between the different types of RUTF in each of the subgroups. Overall, there was no difference between the subgroups ( $\text{Chi}^2 = 1.16$ ,  $\text{df} = 2$ ;  $\text{P} = 0.56$ ;  $\text{I}^2 = 0\%$ ; [Analysis 3.6](#)).

A sensitivity analysis of studies at low risk of bias ([Bahwere 2014](#); [Jones 2015](#); [Kerac 2009](#); [Oakley 2010](#)), only showed no difference between the different types of RUTF formulations (RR 1.03, 95% CI 0.82 to 1.28;  $n = 3166$ ;  $\text{Chi}^2 = 2.95$ ,  $\text{df} = 3$ ;  $\text{P} = 0.4$ ;  $\text{I}^2 = 0\%$ ; 4 studies; analysis not shown), which is in line with the overall pooled effect estimate. A sensitivity analysis with individually randomised studies (all studies for this outcome except [Irena 2015](#)), also showed no difference between the groups (RR 1.02, 95% CI 0.73 to 1.43; 6 studies,  $n = 3428$ ;  $\text{Chi}^2 = 6.06$ ,  $\text{df} = 5$ ;  $\text{P} = 0.3$ ;  $\text{I}^2 = 18\%$ ; analysis not shown) and we obtained a similar result for [Irena 2015](#), the cluster-randomised trial (RR 0.91, 95% CI 0.64 to 1.28; 1 trial,  $n = 881$ ; analysis not shown).

## Secondary outcomes

### Rate of weight gain during intervention

Six studies measured weight gain (g/kg/day) ([Bahwere 2014](#); [Hsieh 2015a](#); [Irena 2015](#); [Kerac 2009](#); [Oakley 2010](#); [Sigh 2018](#)). [Bahwere 2014](#) did not report SD, but we obtained them from the study authors. There was no significant difference between the different RUTF groups (MD 0.11 g/kg/day, 95% CI  $-0.32$  to  $0.54$ ;  $n = 3807$ ; [Analysis 3.7](#)), with significant heterogeneity between the studies ( $\text{Chi}^2 = 19.17$ ;  $\text{df} = 5$ ;  $\text{P value} = 0.002$ ;  $\text{I}^2 = 74\%$ ).

### Subgroup and sensitivity analysis

We found no significant difference in rate of weight gain during the intervention between the different types of RUTF, in each of the subgroups, and no significant difference across pre-trial hospitalisation subgroups ( $\text{Chi}^2 = 1.48$ ;  $\text{df} = 2$ ;  $\text{P value} = 0.48$ ;  $\text{I}^2 = 0\%$ ; [Analysis 3.8](#)), where all children were stabilised as inpatients pre-trial, where some children were hospitalised before the trial, and no children were hospitalised pre-trial.

When performing subgroup analyses for different types of RUTFs, we found significant differences across subgroups ( $\text{Chi}^2 = 5.63$ ;  $\text{df} = 2$ ;  $\text{P value} = 0.06$ ;  $\text{I}^2 = 64.5\%$ ), but did not find a difference in favour of standard or other formulations of RUTF combined ([Analysis 3.9](#)).

1. Less or no milk powder subgroup: MD 0.34 (95% CI  $-0.10$  to  $0.78$ ; 4 studies,  $n = 3015$ ), with significant heterogeneity ( $\text{Chi}^2 = 9.91$ ;  $\text{df} = 3$ ;  $\text{P value} = 0.002$ ;  $\text{I}^2 = 70\%$ )
2. Fatty acids subgroup: MD  $-0.80$  (95% CI  $-1.74$  to  $0.14$ ; 1 trial,  $n = 141$ ; [Hsieh 2015a](#))
3. Pre- and probiotic subgroup: MD  $-0.25$  (95% CI  $-0.87$  to  $0.37$ ; 1 trial,  $n = 651$ ; [Kerac 2009](#)).

Data did not allow us to perform a subgroup analysis by HIV status because the only study ([Kerac 2009](#)), in this comparison, that performed HIV tests on almost all participant children, did not report the results separately for HIV-infected and uninfected children in the subgroup of the study eligible to our review (participants aged 6 to 60 months, see table of [Characteristics of included studies](#) for more information on [Kerac 2009](#)), for this outcome.

A sensitivity analysis with studies at low risk of bias only ([Bahwere 2014](#); [Kerac 2009](#); [Oakley 2010](#)), showed no difference between the different types of RUTF formulations (MD 0.09, 95% CI  $-0.48$  to  $0.65$ ;  $n = 3100$ ;  $\text{Chi}^2 = 7.32$ ,  $\text{df} = 2$ ;  $\text{P} = 0.03$ ;  $\text{I}^2 = 73\%$ ; 3 studies; analysis not shown), which is in line with the overall pooled effect estimate. A sensitivity analysis with individually randomised trials (all studies for this outcome except [Irena 2015](#)), also showed no difference between the groups (MD  $-0.05$ , 95% CI  $-0.5$  to  $0.4$ ; 5 studies,  $n = 3316$ ;  $\text{Chi}^2 = 13.91$ ,  $\text{df} = 4$ ;  $\text{P} = 0.008$ ;  $\text{I}^2 = 71\%$ ; analysis not shown), while the cluster-randomised trial ([Irena 2015](#)), found a difference in favour of the standard RUTF

(MD 1.00, 95% CI 0.37 to 1.63; 1 trial, n = 491; analysis not shown).

#### **Time to recovery (days) during intervention**

Three studies, [Bahwere 2014](#), [Irena 2015](#) and [Kerac 2009](#), measured this outcome in all children, with [Irena 2015](#) also reporting results for the subgroup of children who recovered.

[Bahwere 2014](#) measured time to recovery in days, in all children, during the 16 weeks of intervention. Using the information provided in the trial, we calculated the effect size and found no significant difference between the two RUTF groups (MD 1.90 days, 95% CI -0.82 to 4.62; n = 595; [Analysis 3.10](#)).

[Irena 2015](#) reported a length of stay of 35 days (interquartile range 23 to 49) in the standard RUTF group compared to 35 days (interquartile range 21 to 56) in the other RUTF group, with no significant difference between the groups (P = 0.49). Among the children who recovered, the median length of stay in the standard RUTF group was 35 days (interquartile range 28 to 52) and 47 days (interquartile range 29 to 70) in the RUTF with specific fatty acids group (P value < 0.001; exact P value not reported).

[Kerac 2009](#) reported median days to cure in the eligible subgroup (n = 651) and found no difference (P = 0.66) between the standard RUTF group (median = 38 days; interquartile range 34 to 47) and the RUTF with fatty acids group (median = 37 days; interquartile range 34 to 48).

### **Anthropometrical status**

#### ***Weight-for-height z score (WHZ) during intervention***

Two studies measured WHZ scores after eight weeks of intervention ([Oakley 2010](#); [Sigh 2018](#)), while one trial, [Hsieh 2015a](#), measured the same outcome after 12 weeks of intervention. After pooling the results in a meta-analysis, we found no significant difference between the groups (MD -0.13, 95% CI -0.36 to 0.09; 3 studies, n = 2090; [Analysis 3.11](#)), but there was significant heterogeneity between the studies (Chi<sup>2</sup> = 5.48; df = 2; P value = 0.06; I<sup>2</sup> = 63%).

Another trial, [Jones 2015](#), also measured this outcome and we obtained the change in WHZ score after 12 weeks of intervention from the study authors. The median change in the standard RUTF group (n = 17) was 1.68 (interquartile range 1.17 to 2.73) compared to 1.80 (interquartile range 1.24 to 2.78) in the control RUTF containing specific fatty acids (n = 12).

#### ***Subgroup analysis***

In a subgroup analysis, we found no difference between the group in which some children were hospitalised before the study for stabilisation versus the group in which no children were hospitalised before the study for stabilisation (Chi<sup>2</sup> = 0.05; df = 1; P value =

0.83; I<sup>2</sup> = 0%; 3 studies, n = 2090; [Analysis 3.12](#)). However, in another subgroup analysis, we detected a significant difference (Chi<sup>2</sup> = 4.67; df = 1; P value = 0.03; I<sup>2</sup> = 78.6%; [Analysis 3.13](#)), between studies where the control RUTF had less or no milk powder (MD -0.02, 95% CI -0.11 to 0.08; 2 studies, n = 1949; Chi<sup>2</sup> = 0.81; df = 1; P value = 0.37; I<sup>2</sup> = 0%; [Oakley 2010](#); [Sigh 2018](#)), versus studies where the control RUTF was a standard formulation with specific fatty acids (MD -0.45, 95% CI -0.83 to -0.07; 1 trial, n = 141; [Hsieh 2015a](#)).

#### ***Weight-for-age z score (WAZ) during intervention***

Two studies, [Oakley 2010](#) and [Sigh 2018](#), measured WAZ and reported it as end values at the end of eight weeks of intervention. We combined the data from both studies in a meta-analysis and found no significant difference between the standard and other RUTF groups (MD 0.07, 95% CI -0.06 to 0.20; n = 1949), with no significant heterogeneity between the studies (Chi<sup>2</sup> = 1.13; df = 1; P value = 0.29; I<sup>2</sup> = 12%; [Analysis 3.14](#)).

#### ***Length/height gain (mm/day) during intervention***

Two studies measured length/height gain across eight weeks of intervention ([Oakley 2010](#); [Sigh 2018](#)), while one study measured the same outcome over 12 weeks of intervention ([Hsieh 2015a](#)). After pooling the results in a meta-analysis, we found no significant difference between the groups (MD 0.01, 95% CI -0.09 to 0.10; 3 studies, n = 2090; [Analysis 3.15](#)), but there was significant heterogeneity (Chi<sup>2</sup> = 4.85; df = 2; P value = 0.09; I<sup>2</sup> = 59%).

#### ***Subgroup analysis***

We found no significant difference between subgroups in which either some or no children were hospitalised before the study for stabilisation (Chi<sup>2</sup> = 0.54; df = 1; P value = 0.46; I<sup>2</sup> = 0%; 3 studies, n = 2090; [Analysis 3.16](#)). However, we detected a significant difference (Chi<sup>2</sup> = 4.69; df = 1; P value = 0.03; I<sup>2</sup> = 78.7%; [Analysis 3.17](#)) between studies where the control RUTF had less or no milk powder (MD 0.04, 95% CI 0.02 to 0.06; 2 studies, n = 1949; Chi<sup>2</sup> = 0.16; df = 1; P value = 0.69; I<sup>2</sup> = 0%; [Oakley 2010](#); [Sigh 2018](#)) versus studies where the control RUTF was a standard formulation with specific fatty acids (MD -0.09, 95% CI -0.21 to 0.03; 1 trial, n = 141; [Hsieh 2015a](#)).

#### ***Height-for-age z score (HAZ) during intervention***

When comparing the end values after eight weeks of intervention between standard RUTF and RUTFs with less ([Oakley 2010](#)), or no ([Sigh 2018](#)), milk powder, we detected no significant difference

in HAZ (MD 0.09, 95% CI -0.04 to 0.22; n = 1949; [Analysis 3.18](#)), with no significant heterogeneity ( $\text{Chi}^2 = 0.14$ ;  $\text{df} = 1$ ; P value = 0.71;  $\text{I}^2 = 0\%$ ).

Another trial, [Jones 2015](#), also measured this outcome and we obtained the change in length/height for age after 12 weeks of intervention from the study authors. The median change in the standard RUTF group (n = 18) was 0.18 cm (interquartile range -0.38 to 0.47) compared to 0.34 cm (interquartile range 0.04 to 0.49) in the control RUTF containing specific fatty acids (n = 12).

### **Mid-upper arm circumference (MUAC) gain during intervention**

Two studies measured MUAC gain in mm/day after eight weeks of intervention ([Oakley 2010](#); [Sigh 2018](#)), while one study measured the same outcome after four weeks of intervention ([Hsieh 2015a](#)). After pooling the results in a meta-analysis, we found no significant difference between the groups (MD 0.02, 95% CI -0.02 to 0.07; 3 studies, n = 2089; [Analysis 3.19](#)), and there was significant heterogeneity ( $\text{Chi}^2 = 4.67$ ;  $\text{df} = 2$ ; P value = 0.10;  $\text{I}^2 = 57\%$ ).

For one trial, [Jones 2015](#), we obtained data for the change in mm/day after 12 weeks of intervention from the study authors. The median change in the standard RUTF group (n = 18) was 0.022 mm/day (interquartile range 0.02 to 0.04) compared to 0.029 mm/day (0.02 to 0.02) in the control RUTF with specific fatty acids (n = 12).

### **Subgroup analysis**

In a subgroup analysis, we found no significant difference between subgroups in which either some or no children were hospitalised before the study for stabilisation ( $\text{Chi}^2 = 0.53$ ;  $\text{df} = 1$ ; P value = 0.47;  $\text{I}^2 = 0\%$ ; 3 studies, n = 2089; [Analysis 3.20](#)). However, we detected a significant difference ( $\text{Chi}^2 = 4.67$ ;  $\text{df} = 1$ ; P value = 0.03;  $\text{I}^2 = 78.6\%$ ; [Analysis 3.21](#)) between studies where the control RUTF had less or no milk powder (MD 0.04, 95% CI 0.02 to 0.06; 2 studies, n = 1948;  $\text{Chi}^2 = 0.00$ ;  $\text{df} = 1$ ; P value = 1.00;  $\text{I}^2 = 0\%$ ; [Oakley 2010](#); [Sigh 2018](#)) versus studies where the control RUTF was a standard formulation but containing specific fatty acids (MD -0.07, 95% CI -0.17 to 0.03; 1 trial, n = 141; [Hsieh 2015a](#)).

### **Cognitive function and development**

No study provided data for this outcome.

### **Adverse outcomes**

Four studies reported adverse outcomes ([Bahwere 2014](#); [Hsieh 2015b](#); [Jones 2015](#); [Oakley 2010](#)).

[Bahwere 2014](#) reported no significant difference in the proportion of children with a history of diarrhoea during the first weekly

follow-up visit (RR 0.80, 95% CI 0.55 to 1.15, n = 549; [Analysis 3.22](#)). The overall incidence rate of diarrhoea at the end of the intervention period was similar between groups (P = 0.478): standard RUTF = 11.8 episodes per 100 child visits (range = 142 to 1198); and other RUTF group = 11.5 episodes per 100 child visits (range 146 to 1270).

[Hsieh 2015a](#) reported finding no “adverse reactions” to any of the study foods, while [Jones 2015](#) reported that no “adverse events” were considered to be directly related to the RUTFs and found no significant difference in total illness episodes (P = 0.27) or diarrhoea (P = 0.75) between the experimental and control groups. [Oakley 2010](#) asked caregivers at every fortnightly visit whether the child had had diarrhoea in the previous two weeks, but did not report the results.

### **Acceptability**

Five studies reported on acceptability ([Bahwere 2014](#); [Hsieh 2015b](#); [Irena 2015](#); [Jones 2015](#); [Sigh 2018](#)).

[Hsieh 2015b](#) only measured acceptability as an outcome; it is reported in the same article as [Hsieh 2015a](#). They found no significant difference in the proportion of children giving the highest RUTF likeability score between the standard RUTF and the RUTF with omega-3 fatty acids groups (RR 1.08, 95% CI 0.94 to 1.26, n = 148; [Analysis 3.23](#)). However, significantly less food remained after the taste test among the standard RUTF compared to the omega-3 RUTF groups (MD -2.40 g, 95% CI -4.50 to -0.30; n = 148; [Analysis 3.24](#); [Hsieh 2015b](#)).

[Sigh 2018](#) used a five-point hedonic rating scale to rate how many participants (according to the caregivers) liked or disliked their allocated RUTF. A score of 1 indicated that the child liked the product very much (‘very good’); 2 indicated ‘good’; 3 indicated ‘neutral’; 4 indicated ‘bad’; and 5 indicated ‘very bad’. Acceptability was seen as having a score of 1, 2 or 3. The median score on this scale was 2.0 (interquartile range 2.00 to 3.00) for the standard RUTF and 2.0 (interquartile range 2.0 to 4.0) for the fish-based RUTF. At the first two-weekly visit, the study authors found standard RUTF to be more acceptable than the fish-based RUTF (RR 1.29, 95% CI 1.04 to 1.60; n = 78; [Analysis 3.25](#)). However, for the following three, two-weekly visits during the eight-week treatment period, they detected no difference in likeability between the standard and fish-based RUTF groups.

[Jones 2015](#) (n = 20), measured acceptability as compliance by interview of caregivers and counting full and empty sachets of RUTF at each visit. They reported that the median compliance at the end of the intervention period (day 84) was 90% (interquartile range 80 to 101) in the standard RUTF group compared to 96% (interquartile range 67 to 100) in the group where the RUTF had specific fatty acids (P = 0.98). [Sigh 2018](#) also measured compliance based on “counts of returned RUTF packages” and estimated that 51.7% of participants in the standard RUTF group, compared to 48.1% participants in the fish-based RUTF group, utilised their RUTE. We could not calculate an effect size here because the sample size per group for this outcome was not reported, and the pri-

mary study authors adjusted this finding for age and gender. In [Bahwere 2014](#) and [Irena 2015](#), caregivers were asked at each visit about the acceptability of the standard RUTF compared to formulations with less or no milk powder; however, the results were not reported.

## ADDITIONAL SUMMARY OF FINDINGS *[Explanation]*

| Standard ready-to-use therapeutic food (RUTF) provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet   |  |  |                           |                               |                                  |   |

#### GRADE Working Group grades of evidence

**High quality:** further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

**Low quality:** further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

**Very low quality:** we are very uncertain about the estimate.

<sup>a</sup>Downgraded by one level for imprecision: the 95% CI includes both an important benefit and harm.

<sup>b</sup>Downgraded by one level for inconsistency: I<sup>2</sup> statistic more than 50%.

## DISCUSSION

### Summary of main results

Our review aimed to assess the effects of home-based nutritional rehabilitation with RUTF on recovery, relapse, mortality and rate of weight gain in children aged six months to five years with SAM. We found 15 eligible studies, 14 of which contributed to meta-analyses, and four of which were cluster trials. We addressed three comparisons with a total effective sample size of 6630 children. We judged the overall risk of bias to be high for six studies, unclear for three studies, and low for six studies.

Based on the pooled data from seven studies comparing a standard RUTF at a dosage to meet total daily nutritional requirements with an alternative dietary approach, we conclude that RUTF probably improves recovery from SAM and may increase the rate of weight gain slightly. However, the effects on relapse and mortality are uncertain.

Evidence from two cluster trials indicate that a standard RUTF meeting total daily nutritional requirements, compared with a similar RUTF used as a supplement only, may improve recovery and reduce relapse but its effects on mortality and rate of weight gain are currently unclear.

We found eight studies that compared standard RUTF with RUTFs with alternative formulations (such as using locally available ingredients, containing less or no milk powder, containing specific fatty acids, or with added pre- and probiotics), of which only one focused on RUTF acceptability. For recovery from SAM, it appears to make little or no difference what formulation of RUTF is used. In the case of relapse, however, a standard RUTF seems somewhat more effective. For the outcomes of mortality and rate of weight gain, it probably makes little or no difference whether a standard or alternative formulation of RUTF is used.

### Overall completeness and applicability of evidence

The studies included in this review have a number of limitations in respect of external validity. We sought to evaluate the best evidence regarding the effects of RUTF as home-based treatment for children with SAM. A challenge in this was the completeness of reporting, which we feel ranged from poor to moderate reporting. We were able to obtain some supplementary data from the study authors but a number of important information gaps remain. Particularly, it was not always clear whether study participants had been stabilised in hospital prior to home-based rehabilitation with RUTF (complicated SAM), and whether this was similar across intervention arms. We conducted a subgroup analysis to explore the influence of this factor on the main outcomes across our three comparisons, but this only explained the heterogeneity for the outcome of relapse in Comparison 1. It is plausible that children who first presented with complicated SAM, even though stabilised in

hospital, may be more likely to relapse during the rehabilitation phase. However, the current evidence base does not allow for firm conclusions regarding this issue.

Among the included studies, there is a lack of consistent (routine) testing for HIV and tuberculosis, and reporting on other comorbidities, with appropriate stratification and analysis according to infection status. These comorbidities may have considerable impact on growth, immunity and risk of death, and affected children with these comorbidities may respond differently to SAM treatment (Heikens 2008; Jones 2014; Mody 2014; Trehan 2015).

The included studies assessed a wide age range of children with SAM, but data did not allow for exploration of possible differences in effects across age groups. There is also a lack of information regarding the likelihood of sharing RUTF and control diets with the family, and whether the extent of such sharing differed between comparison groups. In addition, the issue of allergies was not sufficiently addressed. In most studies, children were exposed to peanuts or soy, which are known allergens in children, but few studies reported testing for food allergies.

One of the theoretical benefits of RUTF is its low water availability (and therefore lower risk of contamination with microorganisms), which should lead to fewer episodes of diarrhoea. However, not all studies reported on diarrhoea, despite it being one of the biggest causes of mortality in young children. Furthermore, where studies did report on diarrhoea they measured it in different ways, so that we mostly could not pool data across studies.

With the introduction of the WHO Child Growth Standards in 2006 (WHO 2006), and the change in cut-off for MUAC from 110 mm to 115 mm (Table 1), some children who would have been classified previously as having MAM were classified as SAM (Collins 2006a; Kerac 2009; Seal 2007; WHO/UNICEF 2009). Therefore, studies that were carried out before 2006 (Ciliberto 2005; Manary 2004; Ndekha 2005), or that used older definitions for SAM (Bahwere 2014; Irena 2015; Kerac 2009), or that deviated from the standard WHO definition for SAM (Sigh 2018 used WHZ of  $-2.8$  or less instead of less than  $-3$ ), included a somewhat different profile of participants than studies using the latest (formal) criteria. Furthermore, and also in the earlier studies, antiretroviral drugs for HIV were not readily available in LMICs, and the lack thereof could have influenced HIV-infected children's response to treatment for SAM.

We needed to take into account the type of control group against which standard RUTF was compared. Specifically, for Comparison 3 where different RUTF formulations were compared, we found substantial statistical heterogeneity for the rate of weight gain. Exploration of this heterogeneity by subgroup analysis for the type of control RUTF (studies with less or no milk powder; studies with standard formulation but containing omega-3 fatty acids; studies with standard formulation but with added pre- and probiotics) seems to have accounted for the differences in effects. However, this must be viewed with caution given that data for two of the subgroups were derived from only one trial. In Compari-

son 1, the control groups - being locally available and culturally acceptable foods - differed across studies and could not be subgrouped. However, this resembles 'real life' situations and adds to the generalisability of the findings.

Studies varied in the definition of the main outcome of recovery, and in the duration of the intervention, which could have had an impact on almost all of the review's outcomes. Among the 12 included studies that reported on recovery, only five used the anticipated definition of having a WHZ score of  $-2$  or above (or a similar  $\geq 80\%$  weight for height of the National Center for Health Statistics (NCHS) reference population (Hamil 1979)); two studies used 100% weight for height (NCHS reference population); and the other studies used either weight gain percentage from baseline ( $\geq 15\%$ ,  $\geq 18\%$ ) or MUAC ( $> 11$  cm,  $> 11.5$  cm,  $> 12.4$  cm). Even though we did not detect substantial heterogeneity in the meta-analyses for recovery (Analysis 1.1; Analysis 2.1; Analysis 3.1), it is possible that the different cut-offs for recovery influenced the findings.

The probability of a positive outcome for the review's primary outcomes is likely to be higher with a longer intervention period. On the other hand, for the outcome of rate of weight gain (g/kg/day) where the steepest increase occurs in the first weeks of the rehabilitation phase, studies where weight gain was assessed after four weeks of intervention were more likely to yield better results than those where average weight gain was measured over 16 weeks of intervention. We could not determine the potential long-term effects of RUTF on growth and development as studies generally did not follow up all participants after the end of the intervention period, and no study assessed cognitive function and development, which is important for future school performance. In summary, the current body of evidence for the three comparisons addressed in this review is insufficient to allow evaluation of applicability of the current findings to children with SAM across different ages and levels of severity of SAM, with and without comorbidity. New research (potentially including the 11 ongoing studies identified in this review) might also influence the findings in future review updates.

## Quality of the evidence

We identified selection bias, attrition bias and reporting bias in the included studies as concerns in the majority of the studies. Although we performed sensitivity analyses for the four most important outcomes (Comparisons 1 and 3; data did not allow this for Comparison 2), the interpretation of these are limited due to a relatively small number of studies per comparison and outcome. Using low risk of bias as a marker, the findings of the sensitivity analyses were in line with that of the main analysis for all outcomes, except for relapse in Comparison 3.

For the outcomes of recovery and relapse, a comparison of findings from individually randomised trials with that of cluster-randomised trials showed no difference between the groups for the

individually randomised trials, while the cluster trials found a difference in favour of standard RUTF. For mortality, findings from both types of studies showed no difference between groups, while for rate of weight gain in Comparison 1 the findings from both types of studies favoured RUTF. In Comparison 3, the findings from individually randomised trials showed no difference between groups, whereas the findings from the cluster trials favoured RUTF. Another issue, in terms of the outcomes evaluated, is that while we wanted to report on change from baseline for all continuous outcomes, this was not always possible due to a lack of required information (for example, values at baseline and SD of change). In such cases, we assessed the difference in outcomes between comparison groups at the end of the intervention period. This approach, however, was not ideal given that studies were generally small and many were at high or unclear risk of selection bias.

In our GRADE assessments (Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3), we judged the quality of the evidence for the majority of outcomes (eight) to be very low or low. We judged the quality of the evidence to be moderate for two outcomes and high for two outcomes. Our reasons for downgrading the quality of the evidence varied between comparisons; for Comparisons 1 and 2 we downgraded for risk of bias, indirectness, inconsistency and imprecision; while for Comparison 3 we downgraded for inconsistency and imprecision. The results of our subgroup analyses should be interpreted with caution, as they were based on a smaller number of studies. Also, our main subgroup analysis on pre-trial hospitalisation was not decided a priori. The results of our sensitivity analyses should also be interpreted with caution, as they are likely underpowered to detect differences between experimental and control interventions. This might also be the reason why the effect of the intervention was not statistically significant in some cases.

## Potential biases in the review process

It is unlikely that we have missed any relevant studies since, aside from our electronic searches without any language restriction, we also screened reference lists of included studies and relevant reviews and contacted the corresponding authors of included and ongoing studies (and some of the excluded studies) as well as professionals working in the field.

In our 2013 review (Schoonees 2013), there were two ongoing studies with the same contact author from whom we could not obtain information on study completion or a (published or unpublished) manuscript. The author of another study did not provide us with the manuscript after having indicated an intention to do so. Furthermore, not all studies measured or reported data on recovery, relapse, mortality or rate of weight gain that could be included in a meta-analysis. This was especially problematic in Comparison 1 where, although six of seven studies provided data for the meta-analysis on recovery, we were able to pool data for relapse, mortality and rate of weight gain from only four studies.

Regarding Comparison 3, six of eight studies provided data for the meta-analysis for recovery, relapse and rate of weight gain, and seven for mortality. In Comparison 2, both studies provided data on all four main outcomes for meta-analysis.

We were unable to assess the likelihood of publication bias formally, due to having less than 10 included studies per comparison. None of the review authors have any links to companies that manufacture or sell RUTF; one author is a paediatrician who provides care to patients with SAM.

## Agreements and disagreements with other studies or reviews

To our knowledge, the 2013 version of this review (Schoonees 2013), which included four studies - all conducted in Malawi, was the first systematic review that specifically investigated home-based RUTF for the treatment of children with SAM. For Comparison 1, we found that RUTF may improve recovery (RR 1.33, 95% CI 1.16 to 1.54; moderate-quality evidence) and increase the rate of weight gain slightly (MD 1.12 g/kg/day, 95% CI 0.27 to 1.96; low-quality evidence), but the effects on relapse and mortality are unclear (both very low-quality evidence). This is in line with the findings of this update, except that we also found that standard RUTF may increase the rate of weight gain. In this current review, we did not find any additional studies for Comparison 2, and thus the conclusions did not change. For Comparison 3 in the 2013 review (Schoonees 2013), there was only one eligible trial, which compared RUTF containing 10% milk powder to a standard formulation containing 25% milk powder. There was probably little or no difference between the groups for recovery (RR 0.97, 95% CI 0.93 to 1.01; moderate-quality evidence), but RUTF containing less milk powder may have led to slightly more children relapsing (RR 1.33, 95% CI 1.03 to 1.72; low-quality evidence) and to a lower rate of weight gain (MD -0.5 g/kg/day, 95% CI -0.75 to -0.25; low-quality evidence) than standard RUTF with 25% milk powder. In terms of recovery, this finding is similar to the finding in this update, which shows that it makes little or no difference whether standard or alternative formulation RUTF is used (high-quality evidence). However, in line with the findings of the 2013 review (Schoonees 2013), standard RUTF decreases relapse (RR 0.84, 95% CI 0.72 to 0.98; high-quality evidence). For mortality (RR 1.00, 95% CI 0.8 to 1.24; moderate-quality evidence) and rate of weight gain (MD 0.11 g/kg/day, 95% CI -0.32 to 0.54; low-quality evidence) it may make little or no difference what formulation for RUTF is used.

Gera 2010 assessed the “efficacy and safety of home-based management of SAM using ‘therapeutic nutrition products’ or ready to use therapeutic foods and efficacy of these products in comparison with F-100 and home-based diet” and included two reviews, seven “controlled trials”, seven cohort studies and two consensus statements. The outcomes assessed were recovery rate (as defined by the study authors), weight gain (g/kg/day), relapse, mortality

and morbidities (for example, diarrhoea, malaria and respiratory infections). Of the seven “controlled trials”, we have included two in our review (Ciliberto 2005; Manary 2004). We did not include the remaining five studies because one was facility-based (Diop 2003), three did not have an eligible control group (Diop 2004; Gabouland 2007; Sandige 2004), and one study included Spirulina® and not RUTF (Simpore 2006). Gera 2010 did not perform a meta-analysis of studies on any of the comparisons that we evaluated in our review, but pooled four cohort studies that assessed the effect of home-based RUTF on weight gain in SAM children and found a “mean weight gain” of 3.2 g/kg/day (95% CI 3.06 to 3.34;  $I^2 = 89.8\%$ ) (software used and type of effects model not reported). In this update, we too found that children who received standard RUTF, as opposed to alternative dietary approaches, gained more weight; however, the effect was smaller (MD 1.12 g/kg/day, 95% CI 0.27 to 1.96; random-effects analysis, heterogeneity  $\text{Chi}^2 = 7.40$ ;  $\text{df} = 3$ ;  $P = 0.06$ ;  $I^2 = 59\%$ ; Analysis 1.11).

Guidelines by Ashworth and colleagues categorised weight gain during the rehabilitation phase for children with SAM as poor if less than 5 g/kg/day, moderate if between 5 and 10 g/kg/day and good if more than 10 g/kg/day (Ashworth 2003). The highest average weight gain among our included studies was 5.1 g/kg/day over the first four weeks of the intervention period. This occurred in the study that included only HIV-uninfected children (Manary 2004). Rate of weight gain in children with SAM is complex and depends on a number of different factors. These include the protein quality of the nutritional intervention (Manary 2016); infections and treatment for conditions such as HIV, tuberculosis (Manary 2016), and diarrhoea (Iannotti 2015); and non-dietary factors, such as the mother’s educational status and her knowledge about feeding practices, socioeconomic status, and previous history of malnutrition (Sanghvi 2014). Although rapid weight gain in the rehabilitation phase of SAM is desired, its long-term impact - especially if height gain does not also occur - is of concern in the context of the ‘double burden’ of disease and overnutrition in adulthood (Black 2013; Trehan 2015).

In the same year that our review was first published, Lenters 2013 evaluated the effectiveness of interventions for inpatient management of SAM, community-based management of SAM with RUTE, and interventions for MAM in children under five years of age in LMICs. Lenters and colleagues included the same three studies that were conducted in Malawi that we did (Ciliberto 2005; Manary 2004; Ndekha 2005) and, for their comparison ‘community-based management with RUTF versus “standard therapy”’, came to similar conclusions as reported in our 2013 review (Schoonees 2013). Since then, a number of new studies have been conducted and we have included them in this update. We could not find any other systematic reviews that included the recent studies for home-based rehabilitation with RUTF for young children with SAM. Iannotti 2015 investigated the most effective diagnostic and therapeutic measures for community-based management

of SAM children with diarrhoea; however, their search was done in 2013 and did not identify any studies that directly addressed this question in outpatients.

Although not specifically the focus of our review, it should be noted that RUTF may be used in the context of humanitarian emergencies, where paediatric mortality and morbidity may largely be due to malnutrition (Balhara 2017; Kassebaum 2017; Moss 2006). A systematic review by Balhara and colleagues aimed to characterise specific nutritional interventions in these settings and their effects on paediatric (ages 1 to 18 years) mortality, anthropometric measures and serum markers of nutrition (Balhara 2017). Of the 31 included studies, two studies from Niger (Isanaka 2009; Nackers 2010), and three observational studies from Malawi (Amthor 2009), Myanmar (James 2015), and Sri Lanka (Jayatissa 2012), included RUTF as intervention. We excluded Nackers 2010 from our review because the participants were children with MAM. We also excluded Isanaka 2009 as the study was concerned with the prevention, not treatment, of severe wasting. Balhara 2017 found that “[h]igh- and medium-quality studies demonstrated positive impact of fortified spreads, ready-to-use therapeutic foods, micronutrients supplementation, and food and cash transfers”.

A Cochrane Review evaluated the safety and effectiveness of different types of foods (which included RUTF as a lipid-based nutrient supplement) for children aged six months to five years with MAM in LMICs (Lazzerini 2013), and found no significant difference in mortality (moderate-quality evidence), progression to SAM (high-quality evidence) or in the number of dropouts from the nutritional programme (moderate-quality evidence) when comparing lipid-based nutrient supplements at full dose with any blended foods (without a high lipid content). However, lipid-based supplements significantly increased the number of children who recovered (RR 1.10, 95% CI 1.04 to 1.16; 5 studies, 6367 children; moderate-quality evidence) and decreased the number of “non-recovering children” (quote; RR 0.53, 95% CI 0.40 to 0.69; 3 studies, 4537 children; high-quality evidence). Gera 2017 also evaluated the effectiveness and safety of lipid-based nutrient supplements (which included RUTF) for the treatment of MAM in children aged between six and 59 months. In a subgroup analysis to explore heterogeneity for their primary outcome recovery, they found that the RUTF group had a higher recovery rate than the group consuming RUSF foods (RR 1.23, 95% CI 1.09 to 1.38; 1 trial, 451 children for RUTF and RR 1.06, 95% CI 1.01 to 1.11; 7 studies, 8483 children for RUSF;  $\text{Chi}^2 = 5.17$ ;  $\text{df} = 1$ ;  $P = 0.02$ ;  $I^2 = 80.7\%$  for subgroup differences). Gera and colleagues also reported that lipid-based nutrient supplements containing milk had a higher recovery rate (RR 1.15, 95% CI 1.03 to 1.29; 2 studies, 1140 children) than those without milk (RR 1.06, 95% CI 1.01 to 1.11; 7 studies, 7795 children; heterogeneity indicators not reported).

## Economic commentary

Historically, SAM was managed within healthcare facilities. However, due to the large number of children requiring treatment and limited resources, alternative treatment strategies were sought. Since 2007, WHO has recommended community-based management of malnutrition (CMAM) (WHO/WFP/UNSCN/UNICEF 2007). Mortality rates comparable to those in facility-based care have been reported with this approach (Akparibo 2017; Collins 2002; Collins 2006b; Kabalo 2017). The success of CMAM largely relies on the provision of an adequate and safe therapeutic feed, and RUTF was developed to address this need. A major concern has been the contribution of RUTF to the total cost of CMAM and the effect that it may have on the cost-effectiveness of the programmes. A few studies addressing the cost and cost-effectiveness of community-based management have identified RUTF as one of the most important cost components.

Our searches in 2017 and 2018 yielded 526 records. After screening by two authors independently, we identified seven studies as potentially eligible. All of them evaluated the cost or cost-effectiveness of CMAM and specified the contribution of RUTF to the total cost (Bachmann 2009; Garg 2018; Isanaka 2017; Puett 2013; Rogers 2018; Tekeste 2012; Wilford 2012), and thus we included them in the Economic commentary. Although we did not perform a critical appraisal of these studies, we extracted relevant study information to provide the reader with additional information on the use of RUTF (Table 11).

In Niger, Isanaka and colleagues conducted a cost analysis of in- and outpatient treatment of SAM (Isanaka 2017). RUTF accounted for 44% (EUR 32.98) of the cost of CMAM.

Two studies, one from Zambia (comparing CMAM to no treatment) and the other from Malawi (comparing CMAM to no CMAM), used a decision-tree model to assess cost-effectiveness of CMAM (Bachmann 2009; Wilford 2012). RUTF contributed 36% and 32% respectively to the cost of CMAM in the studies. The incremental cost per death averted was USD 1760 and USD 1365 respectively, and the incremental cost per DALY (disability-adjusted-life year) USD 53 and USD 42.

Another two studies, from Ethiopia (Tekeste 2012), and Bangladesh (Puett 2013), took a societal perspective in their cost-effectiveness analysis, comparing facility-based treatment to community-based treatment. In Ethiopia, RUTF contributed 43.2% to the cost of CMAM whereas in Bangladesh, it was 24%. The authors ascribed the relatively low contribution of RUTF to total costs to the high management costs incurred. The incremental cost of death averted with CMAM in Bangladesh was USD 869 and DALY averted was USD 26; this was significantly less than with inpatient care.

In India, Garg and colleagues conducted a costing analysis of three feeding regimens (two different types of RUTFs and energy-dense, home-prepared food as per Bhandari 2016), for home-based management of children with uncomplicated SAM (Garg 2018). The authors estimated the average cost per treated child in the government setting to be USD 56 (< INR 3500). RUTF contributed

about 65% of this total CMAM cost.

In rural Mali, [Rogers 2018](#) assessed costs and cost-effectiveness of community health worker (CHW)-delivered care and found that CHW-delivered care amounted to approximately half the cost per child treated (USD 244 versus USD 442) and recovered (USD 259 versus USD501) compared to outpatient facility-based care. The data available indicates that CMAM is more cost-effective than facility-based treatment of uncomplicated SAM, despite the relatively high cost of RUTF.

## AUTHORS' CONCLUSIONS

### Implications for practice

Standard ready-to-use therapeutic food (RUTF) probably improves recovery and may increase the rate of weight gain compared to alternative dietary approaches, but its effects on relapse and mortality are unknown. Standard RUTF meeting total daily nutritional requirements may improve recovery and relapse compared to a similar RUTF given as a supplement to the usual diet. However, its effects on mortality and the rate of weight gain are not clear. When comparing RUTFs with different formulations, the current evidence does not favour a particular formulation, except for relapse, which is reduced with standard RUTF. The current limitations in the evidence base do not allow us to draw definitive conclusions regarding the applicability of these findings to children with severe acute malnutrition (SAM) with or without comorbidity and at different ages and levels of severity.

### Implications for research

Well-designed, adequately-powered, pragmatic randomised controlled trials (RCTs) of RUTF are needed, reported according to the [CONSORT guidelines](#), as is more detailed reporting regarding the interventions and their implementation (according to the guidelines given in [Hoffmann 2017](#)). Studies where children are tested and treated for HIV, and where randomisation and analyses are stratified by confirmed HIV status, are needed to explore the

influence of HIV on recovery from SAM. A serious limitation of the existing studies is the use of different definitions of outcomes, such as recovery (different reference or child growth standards and cut-off points), and anthropometrical measurements (assessed at different time points). More attention should be given to the type and standardisation of SAM outcomes in future RUTF research. The focus needs to be on recovery, relapse, mortality and the rate of weight gain, but also on adverse effects, such as diarrhoea and allergic reactions, as these outcomes are important to patients. In addition, cost implications (for example, cost per death averted and cost per disability-adjusted-life year (DALY) averted) should be reported in future studies to enable a cost-effectiveness analysis.

Adherence to RUTF as intervention is unclear; only three included studies reported on compliance, and the selling of dispensed RUTF or sharing it with siblings or other family members is likely. Therefore, future studies could investigate whether a greater effort to promote adherence - and thus higher rate of consumption by the target child - could improve the cost-effectiveness of RUTF treatment.

## ACKNOWLEDGEMENTS

We are grateful to all the primary study authors and their colleagues (of studies included, excluded, ongoing and awaiting assessment) who responded to our email requests. We acknowledge Stéphane Doyon from Médecins Sans Frontières who, for the first version of our review ([Schoonees 2013](#)), provided us with context regarding the use of RUTF in the field. We thank Marianne Visser who helped with data extraction and 'Risk of bias' assessment of cluster-randomised trials. We also thank Margaret Anderson (Information Specialist of Cochrane Developmental, Psychosocial and Learning Problems) and Vittoria Lutje (Information Specialist of Cochrane Infectious Diseases) for their expertise in developing the search strategy and conducting the searches, as well as Paul Garner and Harriet Blundell for their valuable input to the review question.

This review was produced within the Cochrane Developmental, Psychosocial and Learning Problems Group.

## CHARACTERISTICS OF STUDIES

### Characteristics of included studies [ordered by study ID]

#### Bahwere 2014

|               |  |
|---------------|--|
| Methods       | <p><b>Comparison addressed in this review:</b> 3</p> <p><b>Study design:</b> individually randomised, controlled, non-inferiority trial</p> <p><b>Study period:</b> March 2010-March 2011</p> <p><b>Country and setting:</b> central Malawi, 17 outpatient treatment programme sites</p> <p><b>Sample size calculation:</b> yes, used weight gain and recovery</p> <p><b>Child growth standards used for anthropometrical data:</b> not reported (reported anthropometrical data at baseline by using WHZ, WAZ and HAZ)</p> <p><b>Quality of anthropometrical measurements:</b> outcome assessors trained and monitored; weight and MUAC measurements adequately described; length/height measurement not described, only done at baseline</p> <p><b>Tested for peanut allergies:</b> not reported</p>   |
| Participants  | <p><b>Definition used for SAM:</b> MUAC &lt; 11.0 cm or pitting oedema of grade 1 or 2</p> <p><b>Eligible age range:</b> 6-59 months</p> <p><b>All randomised children meet review eligibility criteria:</b> yes</p> <p><b>Total number randomised:</b> 600 children</p> <p><b>Inclusion criteria</b></p> <ol style="list-style-type: none"> <li>1. SAM without complications (medical, dehydration, absence of appetite) or where complications have been resolved</li> </ol> <p><b>Exclusion criteria</b></p> <ol style="list-style-type: none"> <li>1. Children who had been in the study but presented with a new episode of SAM</li> <li>2. Children with any neurological or gastro-intestinal chronic disability</li> </ol> <p><b>HIV and TB status and treatment:</b> HIV was not seen as a complication and an HIV test was offered to all caregivers but not performed systematically. Experimental group: HIV-infected children = 6/112; control group: HIV-infected children = 17/129. Nothing about antiretroviral treatment reported. Nothing about TB comorbidity reported</p> <p><b>Baseline characteristics of experimental group:</b> 154/292 = male; mean age = 24.5 (SD = 10.3) months; previous episode of SAM = 8/292; oedema being the admission criteria = 241/292; mean WAZ = -2.68 (SD = 1.44); mean HAZ = -3.30 (SD = 2.36); mean WHZ = -1.30 (SD = 1.64); mean MUAC = 12.49 (SD = 1.47) cm; diarrhoea = 68/282; fever = 95/279; breastfeeding = not reported</p> <p><b>Baseline characteristics of control group:</b> 145/303 = male; mean age = 25 (SD = 11.0) months; previous episode of SAM = 16/303; oedema being the admission criteria = 249/303; mean WAZ = -2.75 (SD = 1.32); mean HAZ = -3.26 (SD = 2.02); mean WHZ = -1.32 (SD = 1.42); mean MUAC = 12.57 (SD = 1.6) cm; diarrhoea = 71/288; fever = 94/283; breastfeeding = not reported</p> <p><b>Stabilised in hospital before start of trial:</b> children with SAM with complications were first referred to inpatient care and were eligible for study inclusion once they were back at the outpatient department. Experimental group: 8/292; control group: 9/303</p> <p><b>Rehabilitation started in hospital:</b> no</p> |
| Interventions | <p><b>Number of arms:</b> 2</p> <p><b>Maximum intervention duration:</b> 16 weeks</p> <p><b>Sample size experimental group:</b> 292 children randomised</p>  |

|          |   |
|----------|---|
|          | <p><b>Sample size control group:</b> 308 children randomised</p> <p><b>Experimental intervention:</b> “P-RUTF” (quote). “Standard peanut-based RUTF” (quote) manufactured in a factory in Malawi by Valid Nutrition. Contained 25% dried skim milk, 27% sugar, 26% peanut paste, 20% soybean oil; as well as micronutrients. Provided 2218 kJ/100 g, protein = 12% of total energy, fat = 56% of total energy. Packaged in identical 250 g pots. Provided around 732 kJ/kg/day</p> <p><b>Control intervention:</b> “WPC-RUTF” (quote): RUTF with whey protein manufactured in a factory in Malawi by Valid Nutrition. Contained 24% WPC34, 28% sugar, 28% peanut paste, 20% soybean oil; as well as micronutrients. Provided 2218 kJ/100 g, protein = 12% of total energy, fat = 56% of total energy. Packaged in identical 250 g pots. Provided around 732 kJ/kg/day</p> <p><b>Concomitant treatment:</b> all children got a 5-day course of amoxicillin, a single 100 mg dose of deworming medication, and health and nutrition advice</p> <p><b>Risk that intervention was shared with siblings:</b> yes. It is likely that in families who were food insecure, RUTF was shared among siblings. There was the same risk in both groups</p>   |
| Outcomes | <p><b>How often were children assessed during home-based rehabilitation?</b> Once a week</p> <p><b>Followed up after intervention period?</b> No</p> <p><b>Outcomes during or at the end of the intervention period</b></p> <p><b>Primary outcomes</b></p> <ol style="list-style-type: none"> <li><b>Recovery:</b> yes. For children admitted with MUAC &lt; 11.0 cm, recovery was defined as weight gain of at least 15% in relation to baseline weight, MUAC &gt; 11.0 cm, no medical complications, the absence of bilateral pitting oedema and a minimum stay in the programme of 1 month. For children admitted with bilateral pitting oedema, recovery was defined as the absence of bilateral pitting oedema, being clinically well and a MUAC of &gt; 11.0 cm.</li> <li><b>Relapse:</b> yes, defaulters and those lost to follow-up</li> <li><b>Mortality:</b> yes</li> </ol> <p><b>Secondary outcomes</b></p> <ol style="list-style-type: none"> <li><b>Weight gain:</b> yes, rates of weight gain during the entire study period were estimated in g/kg/day and compared between the study arms.</li> <li><b>Time to recovery:</b> yes, length of stay in the trial</li> <li><b>WHZ:</b> no</li> <li><b>WAZ:</b> no</li> <li><b>Height gain:</b> no</li> <li><b>HAZ:</b> no</li> <li><b>MUAC:</b> no</li> <li><b>Cognitive function:</b> no</li> <li><b>Adverse outcomes:</b> diarrhoea, proportion of children with a history of diarrhoea during the first weekly follow-up visit</li> <li><b>Acceptability:</b> yes. caregivers were asked at each visit about the acceptability of the RUTE.</li> </ol> |
| Notes    | <p><b>Trial registry number:</b> not reported</p> <p><b>Type of study report:</b> published journal article</p> <p><b>Contacted study authors:</b> yes. |---|---|--|
| <i>Risk of bias</i>   |   |  |
| Bias  | Authors' judgement  | Support for judgement  |
| Random sequence generation (selection bias)                               | Low risk  | <b>Quote:</b> "A computer-generated sequentially numbered randomisation list (with variable block sizes) that contained both allocations and codes for 700 children was pre-prepared by the trial statistician based outside Malawi and sent to the national study coordinator..."   |
| Allocation concealment (selection bias)                                   | Low risk  | <b>Quote:</b> "...the national study coordinator who then prepared 700 opaque, sealed and consecutively numbered randomisation envelopes. The envelopes were distributed to the enumerator team leaders at study sites in a block of 20 envelopes. In the field, the caretakers were asked to randomly pick a sealed opaque envelope containing the arm code."   |
| Blinding of participants and personnel (performance bias)<br>All outcomes | Low risk  | <b>Quote:</b> "The two RUTFs... were packaged in identical 250-g pots and were labelled with a letter code. The RUTFs were similar in colour, texture and smell. The investigators directly involved in supervision, child recruitment, and management and outcome assessment were blinded to the identity of the letter codes. All non-participating staff of the research sites and the caregivers of enrolled children were also blinded to the identity of the RUTFs." Furthermore, children across groups received the same contact time with study personnel |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Low risk  | <b>Quote:</b> "The investigators directly involved in supervision, child recruitment, and management and outcome assessment were blinded to the identity of the letter codes."   |

|  |              |  |
|--|--------------|--|
| Incomplete outcome data (attrition bias)<br>All outcomes | Unclear risk | <b>Comment:</b> ITT and per-protocol analyses were performed and reported separately. For the ITT analysis, it was not reported how missing data were handled. The denominators for the per-protocol analysis were explained sufficiently on page 442, with 256/292 (87.7%) for the experimental group compared to 266/303 (87.8%) for the control group   |
| Selective reporting (reporting bias)                     | Unclear risk | <b>Comment:</b> protocol or study registration number not reported. In the article's Discussion section, the study authors referred to a protocol: "Although the initial protocol included the assessment of body composition, this objective was later dropped because of financial constraints" (quote). The protocol was not cited. The expected outcomes were pre-specified in the Methods section and reported in the Results section. However, the study authors reported that, at each visit, caregivers were asked about acceptability of the RUTF; however, these results were not reported |
| Other bias   | Low risk     | <b>Comment:</b> more participants in the experimental group were HIV-infected (5.4% (6/112) of the experimental group compared to 13.2% (17/129) in control group). This is likely because of chance, as other baseline characteristics appear similar across groups   |

|               | dren who relapsed were taken up in hospital and restarted the study intervention upon discharge   |
| Interventions | <p><b>Number of arms:</b> 3</p> <p><b>Number of arms used in this review:</b> all 3</p> <p><b>Maximum intervention duration:</b> 16 weeks</p> <p><b>Sample size experimental group:</b> “RUTF-C” (quote) = 298 children randomised; “RUTF-L” (quote) = 307 children randomised</p> <p><b>Sample size control group:</b> 301 children randomised</p> <p><b>Experimental intervention 1:</b> “RUTF-C”. Centrally produced RUTF, manufactured by Compact India. Contained 30% peanut paste, 29% sugar, 20% milk solids, 18% vegetable oil, as well as mineral and vitamin mixes. Provided 2272 kJ/100 g, protein = 15% of total energy, lipids = 34.8% of total energy, carbohydrates = 43.5% of total energy. Smooth texture, and thick and sticky. Packaged in 92 g sachets. Provided around 732 kJ/kg/day</p> <p><b>Experimental intervention 2:</b> “RUTF-L” (quote). Locally produced RUTF (RUTF-L) were prepared at each site, and a consultant who had participated in African studies trained the site teams to produce the RUTF under stringent conditions in a designated room. Contained 26% peanut paste, 27% sugar, 25% milk solids, 20% vegetable oil, as well as mineral and vitamin mixes. Provided 2209 kJ/100 g, protein = 15% of total energy, lipids = 33% of total energy, carbohydrates = 46% of total energy. Thinner consistency than RUTF-C, and granular texture. Packaged in transparent food grade 250 g jars. Provided around 732 kJ/kg/day</p> <p><b>Control intervention:</b> “A-HPF” (quote). Energy-dense home-prepared foods. Families of children were given raw ingredients to prepare foods; ingredients included locally available and acceptable cereals and pulses, sugar, oil, milk and eggs. Recipes for making energy-rich and nutrient-rich foods for children were promoted. A micronutrient preparation was also provided for caregivers to add to the cooked meal before feeding. Amounts in excess of that needed by SAM children were provided, as sharing within the family was expected. Provided around 732 kJ/kg/day for the SAM child</p> <p><b>Concomitant treatment:</b> all children received oral amoxicillin for 5 days; those aged <math>\geq 2</math> years were given deworming medication for 3 days; vitamin A to children with signs or symptoms of a deficiency; immunisation as per the national schedule; children with anaemia (haemoglobin <math>\geq 6</math> to <math>\leq 11</math> g/dL) in the A-HPF group were given iron and folic acid</p> <p><b>Risk that intervention was shared with siblings:</b> yes, in the 2 RUTF groups but not in the control group, as enough raw ingredients were given for sharing within the family</p> |
| Outcomes      | <p><b>How often were children assessed during home-based rehabilitation?</b> Once a week</p> <p><b>Followed up after intervention period?</b> Yes. |---|--|---|
| <b>Risk of bias</b>   |  |   |
| Bias  | Authors' judgement   | Support for judgement   |
| Random sequence generation (selection bias)                               | Unclear risk   | <b>Quote:</b> "Subjects were randomized to either...", but method of randomisation not reported   |
| Allocation concealment (selection bias)                                   | Low risk   | <b>Quote:</b> "Subjects were randomized... by choosing a treatment designation in a sealed envelope, prepared by a study assistant who did not participate in the data collection or analysis."   |
| Blinding of participants and personnel (performance bias)<br>All outcomes | Low risk   | <b>Quote:</b> "The children, caretakers, and clinical workers were blinded to the assigned intervention.", but it is not reported how blinding was done<br><b>Comment:</b> however, it is unlikely that a lack of blinding would have influenced the children's outcomes such as recovery, mortality and anthropometrical outcomes. Also, children from both groups received the same contact time with study personnel |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Unclear risk   | <b>Quote:</b> "...clinical workers were blinded to the assigned intervention."<br><b>Comment:</b> the experimental and control RUTFs were produced in Malawi and France respectively, and it is not reported how blinding was done  |
| Incomplete outcome data (attrition bias)<br>All outcomes                  | Low risk   | <b>Comment:</b> loss to follow-up was somewhat differential, but small: for the experimental group, 6/70 (8.6%), and for the control group, 2/71 (2.8%) dropped out during the 12 weeks of the intervention period  |

Hsieh 2015a (Continued)

|                                      |              |  |
|--------------------------------------|--------------|--|
| Selective reporting (reporting bias) | Unclear risk | <b>Comment:</b> trial registration number: NCT02053857. The expected outcomes were prespecified in the trial registration and Methods section of article, and addressed in Results section. In the Results section, the study authors reported that no “adverse reactions to any of the study foods were reported” (quote). However, it was not prespecified that adverse reactions were measured, and how |
| Other bias                           | Low risk     | <b>Comment:</b> reported baseline characteristics seems to be similar across groups except for the experimental group, in which 11% (8/70) of mothers had HIV-infection compared to 3% (2/71) in the control group, but this is probably because of chance, as other characteristics appear similar across groups  |

|                                      |              | <p>follow-up. Although this is large, as well as differential attrition, “Children who initially accepted the SMS-RUTF but who at a later point in their treatment subsequently refused to eat the SMS-RUTF were transferred to the P-RUTF. These children were kept in the SMS-RUTF group for the intention-to-treat analyses (ITT) but were excluded from the sample for the per protocol (PP) analyses” (quote). It is not reported how missing data for the ITT analyses was handled</p>  |
| Selective reporting (reporting bias) | Unclear risk | <p><b>Comment:</b> trial registration number: IS-RCTN62376241, but it was retrospectively registered. Expected outcomes were prespecified and addressed. However, study authors reported that, at each visit, caregivers were asked about acceptability of the RUTF; however, these results were not reported</p>   |
| Other bias                           | Unclear risk | <p><b>Comment:</b> reported baseline characteristics, except for median MUAC which was significantly higher in the SMS-RUTF (control) group, appeared balanced across groups. Study authors reported that “a greater proportion children in the SMS-RUTF group had oedema, diarrhoea, dehydration or were undergoing TB treatment on admission but these differences were not statistically significant” (quote). Block randomisation with blocks of 4 was done, and in combination with no blinding, this could have posed a risk to selection bias according to section 8.15.1.3 in the <i>Cochrane Handbook of Systematic Reviews of Interventions</i> (Higgins 2017).</p> |

|---|--|--|
| Notes   | <p><b>Trial registry number:</b> CTRI/2014/04/004523<br/> <b>Type of study report:</b> published journal article<br/> <b>Contacted study author:</b> yes. We obtained data for length of hospital stay per group, clarity on the control intervention and duration of the intervention. We also requested SDs for the outcome weight gain, but this was not obtained<br/> <b>Ethics approval:</b> the “Staff Research Society Ethics committee of the LTM Medical College and LTM General Hospital” (quote) approved the trial<br/> <b>Informed consent:</b> informed written consent provided by the caretakers<br/> <b>Financial contributors:</b> Toddler Food Partners based at Minneapolis, USA<br/> <b>Conflict of interest declared:</b> study authors declared they have none.</p> |  |
| <b>Risk of bias</b>   |  |  |
| <b>Bias</b>   | <b>Authors’ judgement</b>  | <b>Support for judgement</b>   |
| Random sequence generation (selection bias)                               | Low risk   | <b>Quote:</b> “...computer generated sequence.. .”, but method of randomisation not reported   |
| Allocation concealment (selection bias)                                   | Unclear risk   | <b>Comment:</b> not reported   |
| Blinding of participants and personnel (performance bias)<br>All outcomes | Low risk   | <b>Comment:</b> blinding not done. However, it is unlikely that the lack of blinding of caregivers and study personnel could have led to high risk of performance bias in children for outcomes such as recovery, weight gain and time to recovery. Children across groups received the same contact time with study personnel |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Unclear risk   | <b>Comment:</b> outcome assessors were not blinded. The majority of outcomes were dependent on anthropometrical measurements. It is unclear how lack of blinding affected outcome measurements   |
| Incomplete outcome data (attrition bias)<br>All outcomes                  | High risk  | <b>Comment:</b> loss to follow-up was not differential across groups (98/174 (56.3%) in experimental group and 85/147 (57.8%) in control group), but the total attrition was large: 321 children were randomised, but only 138 (43%) analysed at the end of the intervention period  |
| Selective reporting (reporting bias)                                      | Unclear risk   | <b>Comment:</b> trial registration number: CTRI/2014/04/004523. More outcomes were reported in the trial registry entry than were reported in the article’s Results section  |

|            |           |   |
|------------|-----------|---|
|            |           | (e.g. number of infection episodes, mortality), and time to recovery was reported in the Results section of the article but was not prespecified in the trial registry entry  |
| Other bias | High risk | <b>Comment:</b> baseline characteristics were reported per group and appear balanced. However, baseline characteristics were only provided for 129/174 and 113/147 for the experimental and control groups respectively |

Study author “SC is an unpaid director of Valid Nutrition, a charity that produces ready-to-use therapeutic food in developing countries” (quote). The other study authors declared no conflicts of interest</p> |  |
|---|---|--|
| <i>Risk of bias</i>   |   |  |
| Bias  | Authors’ judgement  | Support for judgement  |
| Random sequence generation (selection bias)                               | Low risk  | <b>Quote:</b> “A random sequence for the two study groups was computer generated independently of the field team. Permuted blocks of 50 (25 group 1 and 25 group 2 per block) ensured balanced groups for interim safety analysis.”  |
| Allocation concealment (selection bias)                                   | Low risk  | <b>Quote:</b> “An independent volunteer inserted one of two sticky labels (printed group 1 and group 2) into sealed, opaque, sequentially numbered envelopes.”   |
| Blinding of participants and personnel (performance bias)<br>All outcomes | Low risk  | <b>Quote:</b> “...double blind. Taste, colour, and texture of standard (control) and intervention (Synbiotic) food were indistinguishable, so patients were blind to their group allocation... Project field staff were unaware of whether group 1 or 2 contained the Synbiotic.”                                  |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Low risk  | <b>Quote:</b> “They [field staff] were also blind to allocation when assessing or managing a patient.”   |
| Incomplete outcome data (attrition bias)<br>All outcomes                  | Unclear risk  | <b>Comment:</b> loss to follow-up was small and not differential: 33/318 from experimental group compared to 28/333 from control group. However, only a subgroup of randomised participants was eligible to be included in our review, and it is unclear whether randomisation in this smaller group was preserved |
| Selective reporting (reporting bias)                                      | Low risk  | <b>Comment:</b> trial registration number: IS-RCTN19364765. The outcomes prespecified in the trial register were also reported in the Methods section of the article, and addressed in the Results section   |

|            |              |  |
|------------|--------------|--|
| Other bias | Unclear risk | <b>Comment:</b> baseline characteristics reported per group; however, the characteristics of the subgroup of children relevant to our review were not reported |
|------------|--------------|--|

Made from 30% skimmed milk powder, 26% sugar, 2.5% soy oil, 14.5% palm oil, 27% peanuts, with added micronutrients. Provided 2167 kJ per 100 g, 14% protein and 49% fat of total energy; at 837 kJ/kg/day. RUTF packets given weekly to family. In addition to RUTF, children also received feeding counselling and supplementary nutrition (not described) from the Anganwadi, as per guidelines for management for malnutrition under the Integrated Child Development Scheme (ICDS) : 3347 kJ energy and 20-25 g protein/day</p> <p><b>Control intervention:</b> children received feeding counselling and supplementary nutrition (not described) from the Anganwadi, as per guidelines for management for malnutrition</p>  |

|  |  |  |
|--|--|--|
|  | <p>trition under the Integrated Child Development Scheme (ICDS): 3347 kJ energy and 20 to 25 g protein per day</p> <p><b>Concomitant treatment:</b> “case management” (quote) was done, but detail not reported</p> <p><b>Risk that intervention was shared with siblings:</b> it is likely that in families who were food insecure, RUTF was shared among siblings. There was a risk in the experimental group only, although the mothers were asked to “treat RUTF like medicine” (quote) and not to share with siblings</p>   |  |
| <p>Outcomes</p>                                    | <p><b>How often were children assessed during home-based rehabilitation?</b> Once a week</p> <p><b>Followed up after intervention period?</b> No</p> <p><b>Outcomes during or at the end of the intervention period</b></p> <p><b>Primary outcomes</b></p> <ol style="list-style-type: none"> <li>1. <b>Recovery:</b> yes, reaching 115% of baseline weight</li> <li>2. <b>Relapse:</b> no</li> <li>3. <b>Mortality:</b> no</li> </ol> <p><b>Secondary outcomes</b></p> <ol style="list-style-type: none"> <li>1. <b>Weight gain:</b> yes, average change in g/kg/week across the duration of the intervention period</li> <li>2. <b>Time to recovery:</b> no</li> <li>3. <b>WHZ:</b> yes, the study authors measured WHZ and used the data in linear regression, but change or end values per group not reported</li> <li>4. <b>WAZ:</b> no</li> <li>5. <b>Height gain:</b> no</li> <li>6. <b>HAZ:</b> no</li> <li>7. <b>MUAC:</b> no</li> <li>8. <b>Cognitive function:</b> no</li> <li>9. <b>Adverse outcomes:</b> no</li> <li>10. <b>Acceptability:</b> yes, compliance in the experimental group was measured by asking mothers to return empty RUTF packets on a weekly basis</li> </ol> |  |
| <p>Notes</p>                                       | <p><b>Trial registry number:</b> CTRI/2011/12/002259</p> <p><b>Type of study report:</b> published journal article</p> <p><b>Contacted study authors:</b> no</p> <p><b>Ethics approval:</b> yes, “Institute ethics committee approval was obtained” (quote)</p> <p><b>Informed consent:</b> informed consent was obtained from caregivers but it is unclear whether it was provided in writing or orally</p> <p><b>Financial contributors:</b> Indian Association of Preventive and Social Medicine (IAPSM) Ford Foundation Epidemiological Research grant, 2011-12</p> <p><b>Conflict of interest declared:</b> not reported</p>  |  |
| <p><i>Risk of bias</i></p>                         |  |  |
| <p><b>Bias</b></p>                                 | <p><b>Authors’ judgement</b></p>   | <p><b>Support for judgement</b></p>  |
| <p>Random sequence generation (selection bias)</p> | <p>Low risk</p>  | <p><b>Quote:</b> “An independent statistician prepared random sequence using block randomization (block size 4) by randomly selecting the blocks.”; and “...using a computer-generated randomization sequence”</p> |

|   |              |   |
|---|--------------|---|
| Allocation concealment (selection bias)                                   | Low risk     | <p><b>Quote:</b> “Allocation concealment was done using numbered, opaque, sealed envelopes.”</p> <p><b>Comment:</b> not reported whether envelopes were consecutively numbered, but it was probably done</p>  |
| Blinding of participants and personnel (performance bias)<br>All outcomes | Low risk     | <p><b>Quote:</b> “Blinding of study and control group could not be done for obvious reasons.”</p> <p><b>Comment:</b> it is unlikely that the lack of blinding of caregivers and study personnel could have led to a high risk of performance bias in children for outcomes such as recovery and weight gain. Children across groups received similar contact time with study personnel</p>  |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Unclear risk | <p><b>Comment:</b> outcome assessors were not blinded. The majority of outcomes were dependent on anthropometrical measurements. It unclear how lack of blinding affected outcome measurements</p> <p><b>Quote:</b> “We tried to limit bias by asking the medical social worker to measure the children in a separate room before the start of the weekly OTP.”</p>                         |
| Incomplete outcome data (attrition bias)<br>All outcomes                  | Low risk     | <p><b>Comment:</b> no children were lost to follow-up.</p>  |
| Selective reporting (reporting bias)                                      | Unclear risk | <p><b>Comment:</b> trial registration number: CTRI/2011/12/002259. Recovery was the only outcome prespecified in the trial register and in the Methods section of the article. Weight gain was reported in the Results section. WHZ was also measured but results were not reported per group</p>   |
| Other bias  | Unclear risk | <p><b>Comment:</b> few baseline characteristics per group were provided. The WAZ and HAZ scores in the experimental group appear lower than those in the control group, and the experimental group had 23% male participants (3/13) while the control group had 77% (10/13) male participants. Block randomisation with blocks of 4 was done, and in combination with no blinding, this</p> |

could have posed a risk to selection bias according to section 8.15.1.3 in the *Cochrane Handbook of Systematic Reviews of Interventions* (Higgins 2017).

## Sigh 2018

|              |  |
|--------------|--|
| Methods      | <p><b>Comparison addressed in this review:</b> 3</p> <p><b>Study design:</b> individually randomised, controlled, superiority trial</p> <p><b>Study period:</b> September 2015-January 2017</p> <p><b>Country and setting:</b> Cambodia, outpatient department of the National Pediatric Hospital (NPH) in Phnom Penh</p> <p><b>Sample size calculation:</b> yes, using weight gain</p> <p><b>Child growth standards used for anthropometrical data:</b> WHO Child Growth Standards 2006</p> <p><b>Quality of anthropometrical measurements:</b> outcome assessors trained and a well-described digital data collection method used; weight, length/height and MUAC measurements adequately described</p> <p><b>Tested for peanut allergies:</b> not applicable</p>  |
| Participants | <p><b>Definition used for SAM:</b> combination of <math>WHZ \leq -2.8</math> or <math>MUAC \leq 115</math> mm, and presence of nutritional oedema</p> <p><b>Eligible age range:</b> 6-59 months</p> <p><b>All randomised children meet review eligibility criteria:</b> yes</p> <p><b>Total number randomised:</b> 121 children</p> <p><b>Inclusion criteria</b></p> <ol style="list-style-type: none"> <li>1. | <i>Risk of bias</i>   |  |   |
| Bias  | Authors' judgement   | Support for judgement   |
| Random sequence generation (selection bias)                               | Low risk   | <b>Quote:</b> "A computer-generated randomization list in blocks of four patients based on the product codes and patient ID number was made prior to the start of the trial. .."  |
| Allocation concealment (selection bias)                                   | Low risk   | <b>Quote:</b> "The list was provided in a closed envelope to the project manager, who enrolled participants and assigned the intervention to the participants based on the list."   |
| Blinding of participants and personnel (performance bias)<br>All outcomes | Low risk   | <b>Comment:</b> blinding was not done because the experimental and control interventions looked very different. However, it is unlikely that the lack of blinding of caregivers and study personnel could have led to a high risk of performance bias in children for outcomes such as weight and other anthropometrics. Children across groups received the same contact time with study personnel |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Unclear risk   | <b>Comment:</b> outcome assessors were not blinded. The majority of outcomes were dependent on anthropometrical measurements. It is unclear how lack of blinding  |

**Sigh 2018** (Continued)

|  |              | affected outcome measurements   |
|--|--------------|---|
| Incomplete outcome data (attrition bias)<br>All outcomes | High risk    | <b>Comment:</b> although loss to follow-up was not differential, it was large: 23/61 (37.7%) from the experimental group and 24/60 (40%) from the control group   |
| Selective reporting (reporting bias)                     | Unclear risk | <b>Comment:</b> trial registration number: NCT02907424. Weight gain was the primary outcome prespecified in both the trial register and in the Methods section of the article, and reported in the Results section. Regarding the secondary outcomes, some were prespecified in the trial register that were not addressed in the article (e.g. body composition by skinfold thickness and changes in serum concentrations of fatty acids), and vice versa (e.g. change in height, MUAC, WAZ, HAZ)  |
| Other bias   | Unclear risk | <b>Comment:</b> baseline characteristics for all randomised children across groups appear balanced. If children did not eat the RUTF to which they were assigned, the alternative RUTF was offered. This happened in both groups: 2/61 children from the experimental group and 1/60 child from the control group. These children stayed in the study in the other group to which they were randomised. However, for the ITT analysis, they were analysed in the group to which they were randomised. Block randomisation with blocks of 4 was done, and in combination with no blinding, this could have posed a risk to selection bias according to section 8.15.1.3 in the <i>Cochrane Handbook of Systematic Reviews of Interventions</i> (Higgins 2017). |

| <i>Risk of bias</i>                         |   |  |
| <b>Bias</b>                                 | <b>Authors' judgement</b>   | <b>Support for judgement</b>   |
| Random sequence generation (selection bias) | Unclear risk  | <p><b>Quote:</b> "The remaining 112 children having uncomplicated SAM were divided into 2 groups of 56 each by simple randomization."</p> <p><b>Comment:</b> the method of sequence generation was not reported.</p> |
| Allocation concealment (selection bias)     | Unclear risk  | <b>Comment:</b> not reported   |

|   |              |   |
|---|--------------|---|
| Blinding of participants and personnel (performance bias)<br>All outcomes | High risk    | <b>Comment:</b> blinding not done because the experimental and control interventions looked very different. The main focus of the study was acceptability, and a lack of blinding is likely to have influenced performance bias (if the caregivers knew what intervention their child was getting, they could have influenced their child to eat more or less of it, according to their own taste preferences or perception of the product). It is unlikely that a lack of blinding could have influenced changes in weight, height and MUAC outcomes |
| Blinding of outcome assessment (detection bias)<br>All outcomes           | Unclear risk | <b>Comment:</b> outcome assessors were not blinded. The majority of outcomes were dependent on anthropometrical measurements. It is unclear how lack of blinding affected outcome measurements  |
| Incomplete outcome data (attrition bias)<br>All outcomes                  | Low risk     | <b>Comment:</b> while not explicitly reported, it appears that there was no loss to follow-up and that all 112 randomised children (56 per group) completed the trial   |
| Selective reporting (reporting bias)                                      | Unclear risk | <b>Comment:</b> trial registration number: FRAC/Nufl/01, but we could not find this on the Internet and the contact author did not respond to our email. No outcomes prespecified in the Methods section of the article, and recovery, which was the main expected outcome, was not addressed   |
| Other bias  | High risk    | <b>Comment:</b> there are important differences in baseline age and weight between the experimental and control groups (mean age = 25.1 and 32.9 months, mean weight (kg) = 6.44 (SD = 1.6) and 8.69 (SD = 1.76) kg, respectively)  |

## Characteristics of studies awaiting assessment *[ordered by study ID]*

### Huq 2013

|               |   |
|---------------|---|
| Methods       | <p><b>Source:</b> conference abstract</p> <p><b>Design:</b> individually randomised controlled trial</p> <p><b>Study start and end dates:</b> 2009-2012</p> <p><b>Setting:</b> nutrition rehabilitation unit (NRU), but It is unclear whether it was an inpatient setting only, or home-based rehabilitation as well</p> <p><b>Location:</b> Bangladesh, South-East Asia</p> <p><b>Objective:</b> "...to assess the comparative acceptability and efficacy of commercial RUTF (Plumpy'nut®) and rice-lentils based traditional-diets (khichuri and halwa)."</p> <p><b>Sample size:</b> 224 children were randomised equally to 2 groups</p> |
| Participants  | <p><b>Inclusion criteria</b></p> <ol style="list-style-type: none"> <li>1. Children aged 6-24 months with SAM (defined as WHZ &lt; -3 SD or having bipedal nutritional oedema)</li> <li>2. Having an appetite</li> </ol> <p><b>Exclusion criteria:</b> not reported</p>   |
| Interventions | <p><b>Interventions</b></p> <ol style="list-style-type: none"> <li>1. Plumpy'nut® (n = 112)</li> <li>2. Rice-lentils-based traditional diets (khichuri and halwa) (n = 112)</li> </ol> <p><b>Intervention duration:</b> not reported</p> <p><b>Comment:</b> addresses our Comparison 1</p>  |
| Outcomes      | <ol style="list-style-type: none"> <li>1. Oedema-free 15% weight gain</li> <li>2. Duration of hospital stay</li> <li>3. Diarrhoeal episodes</li> </ol> <p><b>Timing of outcome assessment:</b> not reported</p>   |
| Notes         | <p><b>Comment:</b> we emailed the study authors, but were unsuccessful in obtaining a manuscript with more detail</p> <p><b>Sponsors and collaborators:</b> not reported</p>  |

### Kaleem 2014

|              |  |
|--------------|--|
| Methods      | <p><b>Source:</b> published manuscript</p> <p><b>Design:</b> individually randomised controlled trial</p> <p><b>Location:</b> Muzaffargarh, Pakistan</p> <p><b>Study start and end dates:</b> June 2011-June 2012</p> <p><b>Setting:</b> 4 outpatient therapeutic programme (OTP) units. Home-based rehabilitation took place</p> <p><b>Objective:</b> to test "...a special high density diet made from locally available ingredients...against an imported ready to use therapeutic food for the rehabilitation of severely malnourished children"</p> <p><b>Sample size:</b> 270 children</p> |
| Participants | <p><b>Inclusion criteria</b></p> <ol style="list-style-type: none"> <li>1. Children with SAM (MUAC &lt; 11.5 cm or bilateral pitting oedema of grade 1 or 2)</li> <li>2. Aged 6-59 months</li> <li>3. Without medical complications</li> </ol> <p><b>Exclusion criteria</b></p> <ol style="list-style-type: none"> <li>1. Children with "chronic illness" (quote)</li> </ol>   |

|               |  |
|---------------|--|
|               | <ol style="list-style-type: none"> <li>2. Children with medical complications (e.g. severe bilateral oedema grade 3, anorexia, intractable vomiting, lethargy or not alert, high fever (&gt; 100 °F which is about 37.78 °C), convulsions, unconsciousness, severe anaemia, severe dehydration, hypoglycaemia, lower respiratory tract infection, hypothermia)</li> <li>3. Parents not giving informed consent</li> </ol>  |
| Interventions | <p><b>Interventions:</b></p> <ol style="list-style-type: none"> <li>1. Plumpy'nut® (n = 90)</li> <li>2. "locally made high density diet" (quote) (n = 90)</li> <li>3. "high density diet along with micronutrient supplementation" (quote) (n = 90)</li> </ol> <p><b>Intervention duration:</b> 12 weeks</p> <p><b>Comment:</b> the first 2 arms are eligible for our review. Addresses our Comparison 1</p>   |
| Outcomes      | <ol style="list-style-type: none"> <li>1. Recovery</li> <li>2. Relapse</li> <li>3. Weight gain</li> <li>4. Time to recovery</li> </ol> <p><b>Timing of outcome assessment:</b> maximum of 12 weeks</p>   |
| Notes         | <p><b>Comment:</b> the main results for the two relevant groups were exactly the same per group, which we feel is unlikely to have been because of chance or the exact same effects of the interventions. Also, there is a discrepancy in the article for the results of the outcome weight gain, where slightly different results were provided in the table compared to what was reported in the text. There are also some other data errors in the manuscript, where the percentage for the number of events out of the total sample size was not calculated correctly. This raised our concerns about the accuracy of the reporting and we contacted the study author who confirmed that we should use the results in the paper; however, we remain cautious</p> <p><b>Sponsors and collaborators?</b> Not explicitly reported. Study authors mentioned that "Unfortunately standard therapy is not widely available in Pakistan. A few Nutritional Rehabilitation Units (NRUs) are functional and these are mostly supported and funded by international agencies." (quote)</p> |

**MUAC:** mid-upper arm circumference; **NRU:** nutrition rehabilitation unit; **OTP:** outpatient therapeutic programme; **RUTF:** ready-to-use therapeutic food; **SAM:** severe acute malnutrition; **SD:** standard deviation; **WHZ:** weight for height z score;

## DATA AND ANALYSES

### Comparison 1. Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

| Outcome or subgroup title  | No. of studies | No. of participants | Statistical method                   | Effect size         |
|--|----------------|---------------------|--------------------------------------|---------------------|
| 1 Recovery during intervention   | 6              | 1852                | Risk Ratio (M-H, Random, 95% CI)     | 1.33 [1.16, 1.54]   |
| 2 Recovery during intervention: pre-trial hospitalisation subgroups          | 6              | 1852                | Risk Ratio (M-H, Random, 95% CI)     | 1.33 [1.16, 1.54]   |
| 2.1 All children hospitalised pre-trial                                      | 3              | 568                 | Risk Ratio (M-H, Random, 95% CI)     | 1.41 [1.04, 1.92]   |
| 2.2 Some children hospitalised pre-trial                                     | 2              | 1258                | Risk Ratio (M-H, Random, 95% CI)     | 1.30 [1.08, 1.57]   |
| 2.3 No children hospitalised pre-trial                                       | 1              | 26                  | Risk Ratio (M-H, Random, 95% CI)     | 6.0 [0.83, 43.13]   |
| 3 Recovery at follow-up  | 2              | 907                 | Risk Ratio (M-H, Random, 95% CI)     | 1.10 [0.83, 1.46]   |
| 4 Relapse during intervention  | 4              | 1505                | Risk Ratio (M-H, Random, 95% CI)     | 0.55 [0.30, 1.01]   |
| 5 Relapse during intervention: pre-trial hospitalisation subgroups           | 4              | 1505                | Risk Ratio (M-H, Random, 95% CI)     | 0.55 [0.30, 1.01]   |
| 5.1 All children hospitalised pre-trial                                      | 2              | 247                 | Risk Ratio (M-H, Random, 95% CI)     | 0.34 [0.17, 0.66]   |
| 5.2 Some children hospitalised pre-trial                                     | 2              | 1258                | Risk Ratio (M-H, Random, 95% CI)     | 0.83 [0.53, 1.30]   |
| 6 Relapse during intervention: factory- versus local site-produced subgroups | 4              | 1505                | Risk Ratio (M-H, Random, 95% CI)     | 0.65 [0.41, 1.01]   |
| 6.1 Factory-produced   | 4              | 1048                | Risk Ratio (M-H, Random, 95% CI)     | 0.56 [0.29, 1.06]   |
| 6.2 Local site-produced  | 1              | 457                 | Risk Ratio (M-H, Random, 95% CI)     | 0.83 [0.51, 1.33]   |
| 7 Relapse during intervention: HIV status subgroups                          | 4              | 1505                | Risk Ratio (M-H, Random, 95% CI)     | 0.55 [0.30, 1.01]   |
| 7.1 HIV-uninfected or untested   | 3              | 1440                | Risk Ratio (M-H, Random, 95% CI)     | 0.62 [0.34, 1.15]   |
| 7.2 HIV-infected   | 1              | 65                  | Risk Ratio (M-H, Random, 95% CI)     | 0.26 [0.07, 1.04]   |
| 8 Relapse at follow-up   | 1              |                     | Risk Ratio (M-H, Random, 95% CI)     | Totals not selected |
| 9 Mortality during intervention  | 4              | 1505                | Risk Ratio (M-H, Random, 95% CI)     | 1.05 [0.51, 2.16]   |
| 10 Mortality during intervention: pre-trial hospitalisation subgroups        | 4              | 1505                | Risk Ratio (M-H, Random, 95% CI)     | 1.05 [0.51, 2.16]   |
| 10.1 All children hospitalised pre-trial                                     | 2              | 247                 | Risk Ratio (M-H, Random, 95% CI)     | 1.47 [0.53, 4.04]   |
| 10.2 Some children hospitalised pre-trial                                    | 2              | 1258                | Risk Ratio (M-H, Random, 95% CI)     | 0.86 [0.20, 3.73]   |
| 11 Rate of weight gain (g/kg/day) during intervention                        | 4              | 1450                | Mean Difference (IV, Random, 95% CI) | 1.12 [0.27, 1.96]   |

|   |   |      |                                      |                       |
|---|---|------|--------------------------------------|-----------------------|
| 12 Rate of weight gain (g/kg/day) during intervention: pre-trial hospitalisation subgroups          | 4 | 1450 | Mean Difference (IV, Random, 95% CI) | 1.12 [0.27, 1.96]     |
| 12.1 All children hospitalised pre-trial  | 2 | 243  | Mean Difference (IV, Random, 95% CI) | 1.57 [0.32, 2.82]     |
| 12.2 Some children hospitalised pre-trial   | 2 | 1207 | Mean Difference (IV, Random, 95% CI) | 0.65 [0.16, 1.14]     |
| 13 Rate of weight gain (g/kg/day) during intervention: factory-versus local site-produced subgroups | 4 | 1450 | Mean Difference (IV, Random, 95% CI) | 1.00 [0.34, 1.66]     |
| 13.1 Factory-produced   | 4 | 1018 | Mean Difference (IV, Random, 95% CI) | 1.05 [0.08, 2.02]     |
| 13.2 Local site-produced  | 1 | 432  | Mean Difference (IV, Random, 95% CI) | 0.88 [0.15, 1.61]     |
| 14 Rate of weight gain (g/kg/day) during intervention: HIV status subgroups                         | 4 | 1450 | Mean Difference (IV, Random, 95% CI) | 1.12 [0.27, 1.96]     |
| 14.1 HIV-uninfected or untested   | 3 | 1385 | Mean Difference (IV, Random, 95% CI) | 1.20 [0.08, 2.33]     |
| 14.2 HIV-infected   | 1 | 65   | Mean Difference (IV, Random, 95% CI) | 0.80 [-0.64, 2.24]    |
| 15 Time to recovery (days) during intervention  | 2 | 556  | Mean Difference (IV, Random, 95% CI) | -7.61 [-12.84, -2.37] |
| 16 Weight-for-height z score (WHZ) during intervention  | 1 |      | Mean Difference (IV, Random, 95% CI) | Totals not selected   |
| 17 WHZ at follow-up   | 2 | 937  | Mean Difference (IV, Random, 95% CI) | 0.06 [-0.04, 0.16]    |
| 18 Length/height gain (mm/day) during intervention  | 2 | 417  | Mean Difference (IV, Random, 95% CI) | 0.12 [-0.00, 0.24]    |
| 19 Height-for-age z score (HAZ) at follow-up  | 1 |      | Mean Difference (IV, Random, 95% CI) | Totals not selected   |
| 20 Mid-upper arm circumference (MUAC) gain (mm/day) during intervention                             | 3 | 570  | Mean Difference (IV, Random, 95% CI) | 0.13 [0.04, 0.21]     |
| 21 MUAC gain (cm) at follow-up  | 1 |      | Mean Difference (IV, Random, 95% CI) | Totals not selected   |
| 22 Diarrhoea events during intervention   | 1 |      | Risk Ratio (M-H, Random, 95% CI)     | Totals not selected   |
| 23 Days of diarrhoea during intervention  | 1 |      | Mean Difference (IV, Random, 95% CI) | Totals not selected   |
| 24 Acceptability  | 1 |      | Risk Ratio (M-H, Random, 95% CI)     | Totals not selected   |

## Comparison 2. Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

| Outcome or subgroup title      | No. of studies | No. of participants | Statistical method               | Effect size       |
|--------------------------------|----------------|---------------------|----------------------------------|-------------------|
| 1 Recovery during intervention | 2              | 210                 | Risk Ratio (M-H, Random, 95% CI) | 1.41 [1.19, 1.68] |
| 1.1 HIV-uninfected children    | 1              | 162                 | Risk Ratio (M-H, Random, 95% CI) | 1.38 [1.15, 1.67] |
| 1.2 HIV-infected children      | 1              | 48                  | Risk Ratio (M-H, Random, 95% CI) | 1.62 [1.01, 2.59] |
| 2 Relapse during intervention  | 2              | 210                 | Risk Ratio (M-H, Random, 95% CI) | 0.11 [0.01, 0.85] |
| 2.1 HIV-uninfected children    | 1              | 162                 | Risk Ratio (M-H, Random, 95% CI) | 0.07 [0.00, 1.10] |

Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age (Review)

122

|  |   |     |                                      |                     |
|--|---|-----|--------------------------------------|---------------------|
| 2.2 HIV-infected children                            | 1 | 48  | Risk Ratio (M-H, Random, 95% CI)     | 0.20 [0.01, 3.62]   |
| 3 Mortality during intervention                      | 2 | 210 | Risk Ratio (M-H, Random, 95% CI)     | 1.36 [0.46, 4.04]   |
| 3.1 HIV-uninfected children                          | 1 | 162 | Risk Ratio (M-H, Random, 95% CI)     | 2.07 [0.36, 12.07]  |
| 3.2 HIV-infected children                            | 1 | 48  | Risk Ratio (M-H, Random, 95% CI)     | 1.05 [0.26, 4.18]   |
| 4 Rate of weight gain (g/kg/day) during intervention | 2 | 206 | Mean Difference (IV, Random, 95% CI) | 1.21 [-0.74, 3.16]  |
| 4.1 HIV-uninfected children                          | 1 | 158 | Mean Difference (IV, Random, 95% CI) | 2.10 [1.12, 3.08]   |
| 4.2 HIV-infected children                            | 1 | 48  | Mean Difference (IV, Random, 95% CI) | 0.10 [-1.53, 1.73]  |
| 5 Time to recovery (days) during intervention        | 1 |     | Mean Difference (IV, Random, 95% CI) | Totals not selected |
| 6 WHZ at follow-up                                   | 1 |     | Mean Difference (IV, Random, 95% CI) | Totals not selected |
| 7 Length/height gain (mm/day) during intervention    | 1 |     | Mean Difference (IV, Random, 95% CI) | Totals not selected |
| 8 MUAC gain (mm/day) during intervention             | 2 | 173 | Mean Difference (IV, Random, 95% CI) | 0.11 [-0.01, 0.22]  |
| 8.1 HIV-uninfected children                          | 1 | 125 | Mean Difference (IV, Random, 95% CI) | 0.15 [0.03, 0.27]   |
| 8.2 HIV-infected children                            | 1 | 48  | Mean Difference (IV, Random, 95% CI) | 0.03 [-0.14, 0.20]  |

### Comparison 3. Standard RUTF versus RUTF using an alternative formulation

| Outcome or subgroup title  | No. of studies | No. of participants | Statistical method               | Effect size       |
|--|----------------|---------------------|----------------------------------|-------------------|
| 1 Recovery during intervention                                       | 6              | 4188                | Risk Ratio (M-H, Random, 95% CI) | 1.03 [0.99, 1.08] |
| 2 Recovery during intervention: pre-trial hospitalisation subgroups  | 6              | 4188                | Risk Ratio (M-H, Random, 95% CI) | 1.03 [0.99, 1.08] |
| 2.1 All children hospitalised pre-trial                              | 1              | 651                 | Risk Ratio (M-H, Random, 95% CI) | 0.95 [0.83, 1.09] |
| 2.2 Some children hospitalised pre-trial                             | 2              | 641                 | Risk Ratio (M-H, Random, 95% CI) | 1.09 [0.85, 1.39] |
| 2.3 No children hospitalised pre-trial                               | 3              | 2896                | Risk Ratio (M-H, Random, 95% CI) | 1.06 [0.99, 1.14] |
| 3 Relapse during intervention  | 6              | 4188                | Risk Ratio (M-H, Random, 95% CI) | 0.84 [0.72, 0.98] |
| 4 Relapse during intervention: pre-trial hospitalisation subgroups   | 6              | 4188                | Risk Ratio (M-H, Random, 95% CI) | 0.84 [0.72, 0.98] |
| 4.1 All children hospitalised pre-trial                              | 1              | 651                 | Risk Ratio (M-H, Random, 95% CI) | 0.96 [0.66, 1.40] |
| 4.2 Some children hospitalised pre-trial                             | 2              | 641                 | Risk Ratio (M-H, Random, 95% CI) | 0.81 [0.44, 1.52] |
| 4.3 No children hospitalised pre-trial                               | 3              | 2896                | Risk Ratio (M-H, Random, 95% CI) | 0.81 [0.68, 0.97] |
| 5 Mortality during intervention                                      | 7              | 4309                | Risk Ratio (M-H, Random, 95% CI) | 1.00 [0.80, 1.24] |
| 6 Mortality during intervention: pre-trial hospitalisation subgroups | 7              | 4309                | Risk Ratio (M-H, Random, 95% CI) | 1.00 [0.80, 1.24] |
| 6.1 All children hospitalised pre-trial                              | 1              | 651                 | Risk Ratio (M-H, Random, 95% CI) | 1.11 [0.86, 1.43] |

|   |   |      |                                      |                      |
|---|---|------|--------------------------------------|----------------------|
| 6.2 Some children hospitalised pre-trial  | 3 | 762  | Risk Ratio (M-H, Random, 95% CI)     | 0.60 [0.16, 2.33]    |
| 6.3 No children hospitalised pre-trial  | 3 | 2896 | Risk Ratio (M-H, Random, 95% CI)     | 0.94 [0.67, 1.34]    |
| 7 Rate of weight gain (g/kg/day) during intervention  | 6 | 3807 | Mean Difference (IV, Random, 95% CI) | 0.11 [-0.32, 0.54]   |
| 8 Rate of weight gain (g/kg/day) during intervention: pre-trial hospitalisation subgroups       | 6 | 3807 | Mean Difference (IV, Random, 95% CI) | 0.11 [-0.32, 0.54]   |
| 8.1 All children hospitalised pre-trial   | 1 | 651  | Mean Difference (IV, Random, 95% CI) | -0.25 [-0.87, 0.37]  |

### Analysis 1.1. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 1 Recovery during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 1 Recovery during intervention

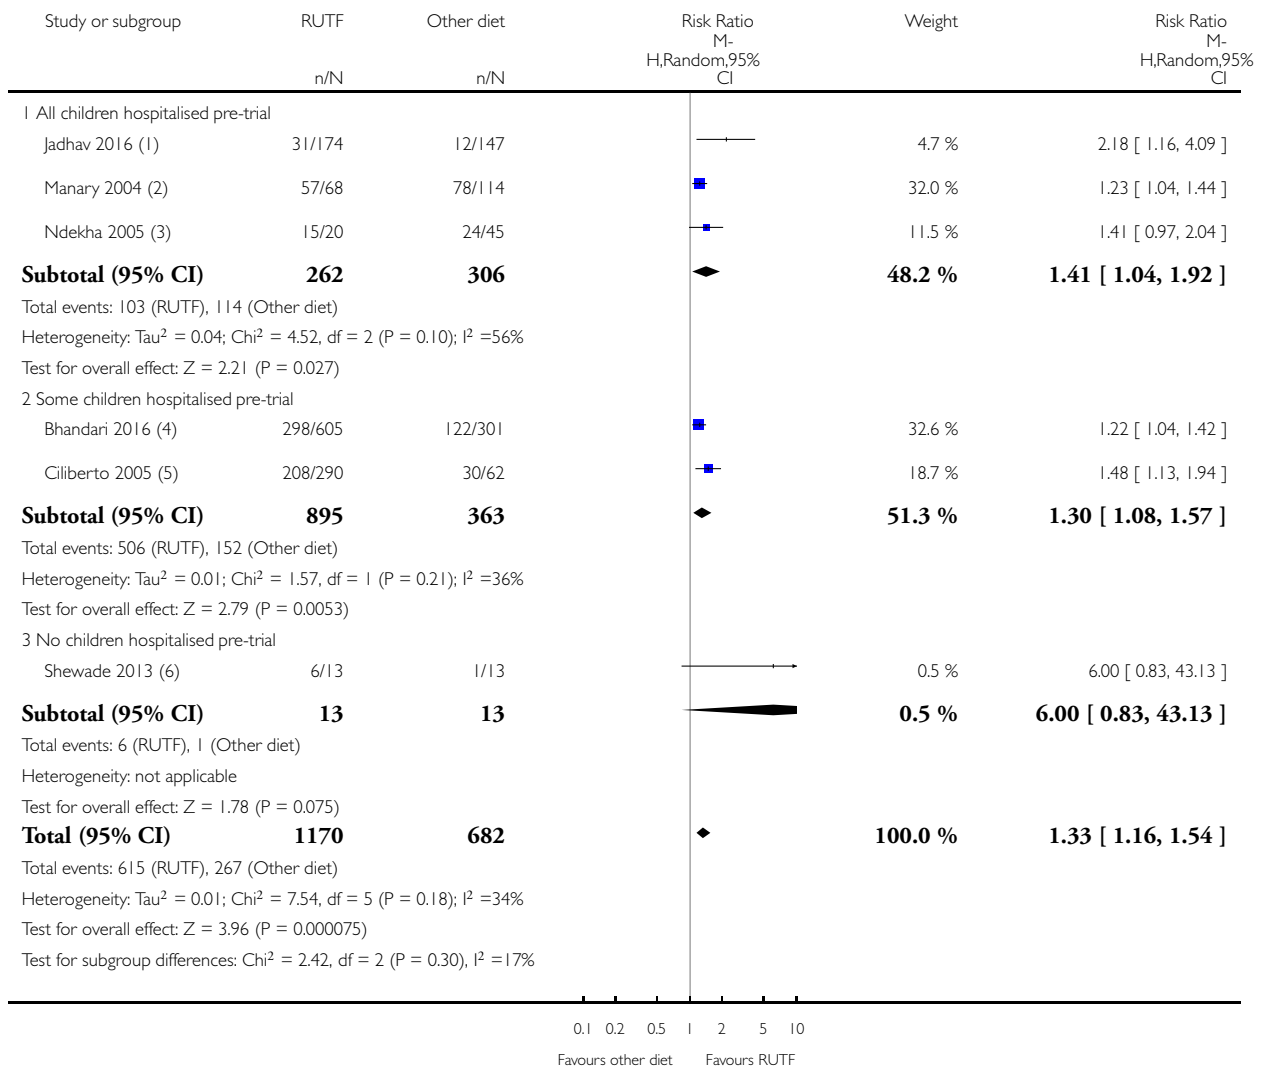

- (1) WHZ  $\geq$  -2 and absence of oedema within 16 weeks of intervention.
- (2) WHZ > -2 and without oedema, relapse or death within 8 weeks of intervention.
- (3) WHZ > -2 within 8 weeks of intervention.
- (4) HIV-uninfected; WHZ > 0 within 16 weeks of intervention.
- (5) HIV-infected; 100% weight for height within "some weeks" of intervention.
- (6) Reaching 115% of baseline weight within 12 weeks of intervention.

**Analysis 1.2. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 2 Recovery during intervention: pre-trial hospitalisation subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 2 Recovery during intervention: pre-trial hospitalisation subgroups

- (1) WHZ > -2 within 8 weeks of intervention.
- (2) HIV-uninfected; WHZ > 0 within 16 weeks of intervention.
- (3) HIV-infected; 100% weight for height within "some weeks" of intervention.
- (4) WHZ  $\geq$  -2 and absence of oedema within 16 weeks of intervention.
- (5) WHZ > -2 and without oedema, relapse or death within 8 weeks of intervention.
- (6) 115% of baseline weight within 12 weeks of intervention.

### Analysis 1.3. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 3 Recovery at follow-up.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 3 Recovery at follow-up

- (1) WHZ  $\geq$  -2 at 16 weeks after the intervention period.
- (2) WHZ > -2 at 6 months after the intervention period.

**Analysis 1.4. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 4 Relapse during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 4 Relapse during intervention

- (1) Children hospitalised and lost to follow-up over 16 weeks of intervention.
- (2) Recurrence of oedema or systemic infection over 8 weeks of intervention.
- (3) HIV-uninfected; recurrence of oedema or systemic infection over 16 weeks of intervention.
- (4) HIV-infected; hospitalisation and lost to follow-up over "some weeks" of intervention.

**Analysis 1.5. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 5 Relapse during intervention: pre-trial hospitalisation subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 5 Relapse during intervention: pre-trial hospitalisation subgroups

(1) HIV-uninfected; recurrence of oedema or systemic infection over 16 weeks of intervention.

(2) HIV-infected; hospitalisation and lost to follow-up over "some weeks" of intervention.

(3) Children hospitalised and lost to follow-up over 16 weeks of intervention.

(4) Recurrence of oedema or systemic infection over 8 weeks of intervention.

**Analysis 1.6. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 6 Relapse during intervention: factory- versus local site-produced subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 6 Relapse during intervention: factory- versus local site-produced subgroups

- (1) Children hospitalised and lost to follow-up over 16 weeks of intervention.
- (2) Recurrence of oedema or systemic infection over 8 weeks of intervention.
- (3) HIV-uninfected; recurrence of oedema or systemic infection over 16 weeks of intervention.
- (4) HIV-infected; hospitalisation and lost to follow-up over "some weeks" of intervention.
- (5) Children hospitalised and lost to follow-up over 16 weeks of intervention.

**Analysis 1.7. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 7 Relapse during intervention: HIV status subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 7 Relapse during intervention: HIV status subgroups

- (1) Children hospitalised and lost to follow-up over 16 weeks of intervention.
- (2) Recurrence of oedema or systemic infection over 8 weeks of intervention.
- (3) HIV-uninfected; recurrence of oedema or systemic infection over 16 weeks of intervention.
- (4) HIV-infected; hospitalisation and lost to follow-up over "some weeks" of intervention.

**Analysis 1.8. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 8 Relapse at follow-up.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 8 Relapse at follow-up

(1) Children hospitalised during the 16 weeks after the intervention period.

**Analysis 1.9. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 9 Mortality during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 9 Mortality during intervention

- (1) Reasons for deaths not reported.
- (2) All death considered to be a consequence of malnutrition.
- (3) HIV-uninfected; reasons for death not reported.
- (4) HIV-infected; reasons for death not reported.

**Analysis 1.10. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 10 Mortality during intervention: pre-trial hospitalisation subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 10 Mortality during intervention: pre-trial hospitalisation subgroups

- (1) HIV-uninfected; reasons for death not reported.
- (2) HIV-infected; reasons for death not reported.
- (3) Reasons for deaths not reported.
- (4) All death considered to be a consequence of malnutrition.

**Analysis 1.11. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 11 Rate of weight gain (g/kg/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 11 Rate of weight gain (g/kg/day) during intervention

- (1) Change between baseline and recovery or 16 weeks of intervention, whichever was earlier.
- (2) Change between baseline and week 4 of 8 weeks of intervention.
- (3) HIV-uninfected; change between baseline and week 4 of 16 weeks of intervention.
- (4) HIV-infected; change between baseline and week 4 of intervention that lasted for "some weeks".

**Analysis I.12. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 12 Rate of weight gain (g/kg/day) during intervention: pre-trial hospitalisation subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 12 Rate of weight gain (g/kg/day) during intervention: pre-trial hospitalisation subgroups

(1) HIV-uninfected; change between baseline and week 4 of 16 weeks of intervention.

(2) HIV-infected; change between baseline and week 4 of intervention that lasted for "some weeks".

(3) Change between baseline and recovery or 16 weeks of intervention, whichever was earlier.

(4) Change between baseline and week 4 of 8 weeks of intervention.

**Analysis I.13. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 13 Rate of weight gain (g/kg/day) during intervention: factory- versus local site-produced subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 13 Rate of weight gain (g/kg/day) during intervention: factory- versus local site-produced subgroups

(1) Change between baseline and recovery or 16 weeks of intervention, whichever was earlier.

(2) Change between baseline and week 4 of 8 weeks of intervention.

(3) HIV-uninfected; change between baseline and week 4 of 16 weeks of intervention.

(4) HIV-infected; change between baseline and week 4 of intervention that lasted for "some weeks".

(5) Change between baseline and recovery or 16 weeks of intervention, whichever was earlier.

**Analysis I.14. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 14 Rate of weight gain (g/kg/day) during intervention: HIV status subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 14 Rate of weight gain (g/kg/day) during intervention: HIV status subgroups

(1) Change between baseline and recovery or 16 weeks of intervention, whichever was earlier.

(2) Change between baseline and week 4 of 8 weeks of intervention.

(3) HIV-uninfected; change between baseline and week 4 of 16 weeks of intervention.

(4) HIV-infected; change between baseline and week 4 of intervention that lasted for "some weeks".

**Analysis I.15. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 15 Time to recovery (days) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 15 Time to recovery (days) during intervention

(1) Only measured in those who recovered.

(2) HIV-uninfected; only measured in those who recovered.

**Analysis I.16. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 16 Weight-for-height z score (WHZ) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 16 Weight-for-height z score (WHZ) during intervention

(1) End values, probably after 8 weeks of intervention.

### Analysis 1.17. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 17 WHZ at follow-up.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 17 WHZ at follow-up

(1) Change between enrolment and 16 weeks after the intervention ended.

(2) HIV-uninfected; end values among recovered children who were assessed 6 months after the intervention.

**Analysis I.18. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 18 Length/height gain (mm/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 18 Length/height gain (mm/day) during intervention

(1) Change in "height gain" over 8 weeks of intervention.

(2) Change in "statural growth" over first 4 weeks of "some weeks" of intervention.

**Analysis I.19. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 19 Height-for-age z score (HAZ) at follow-up.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 19 Height-for-age z score (HAZ) at follow-up

(1) Change between enrolment and 16 weeks after the intervention ended.

**Analysis 1.20. Comparison 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 20 Mid-upper arm circumference (MUAC) gain (mm/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 1 Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 20 Mid-upper arm circumference (MUAC) gain (mm/day) during intervention

- (1) Change between baseline and end of week 4 of 8 weeks of intervention.
- (2) HIV-uninfected; change between baseline and week 4 of 16 weeks of intervention.
- (3) HIV-infected; change between baseline and week 4 of "some weeks" of intervention.

**Analysis I.21. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 21 MUAC gain (cm) at follow-up.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 21 MUAC gain (cm) at follow-up

(1) Change between baseline and 16 weeks after intervention period.

**Analysis I.22. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 22 Diarrhoea events during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 22 Diarrhoea events during intervention

(1) Measured at any time during the 16 weeks of intervention.

**Analysis I.23. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 23 Days of diarrhoea during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 23 Days of diarrhoea during intervention

(1) Measured over the first two weeks of the 8 week intervention period.

**Analysis I.24. Comparison I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach, Outcome 24 Acceptability.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: I Standard RUTF provided at a dose that meets total daily nutritional requirements versus an alternative dietary approach

Outcome: 24 Acceptability

(1) Caregivers were asked daily how eagerly their children accepted the intervention.

## Analysis 2.1. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 1 Recovery during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 1 Recovery during intervention

(1) WHZ > 0 within 16 weeks of intervention.

(2) Reaching 100% weight for height within "some weeks" of intervention.

## Analysis 2.2. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 2 Relapse during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 2 Relapse during intervention

(1) Recurrence of oedema or systemic infection over 16 weeks of intervention.

(2) Hospitalisation and lost to follow-up over "some weeks" of intervention.

**Analysis 2.3. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 3 Mortality during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 3 Mortality during intervention

(1) HIV-uninfected; reasons for death not reported.

(2) HIV-infected; reasons for death not reported.

**Analysis 2.4. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 4 Rate of weight gain (g/kg/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 4 Rate of weight gain (g/kg/day) during intervention

(1) Change between baseline and week 4 of 16 weeks of intervention.

(2) Change between baseline and week 4 of intervention that lasted for "some weeks".

**Analysis 2.5. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 5 Time to recovery (days) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 5 Time to recovery (days) during intervention

(1) HIV-uninfected; only measured in those who recovered.

**Analysis 2.6. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 6 WHZ at follow-up.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 6 WHZ at follow-up

(1) HIV-uninfected; end values among recovered children who were assessed at follow-up, 6 months after the intervention.

**Analysis 2.7. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 7 Length/height gain (mm/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 7 Length/height gain (mm/day) during intervention

(1) Change in "statural growth" over first 4 weeks of "some weeks" of intervention.

**Analysis 2.8. Comparison 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet, Outcome 8 MUAC gain (mm/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 2 Standard RUTF provided at a dose that meets total daily nutritional requirements versus as a supplement to the usual diet

Outcome: 8 MUAC gain (mm/day) during intervention

(1) HIV-uninfected; change over first 4 weeks of 16 weeks of intervention.

(2) HIV-infected; change over first 4 weeks of "some weeks" of intervention.

### Analysis 3.1. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 1 Recovery during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 1 Recovery during intervention

(1) Weight gain  $\geq$  15%, absence of medical complications and oedema, MUAC > 11.0 cm within 16 weeks of intervention.

(2) MUAC > 12.4 cm without oedema within 12 weeks.

(3) Weight gain  $\geq$  18%, absence of medical complications and oedema, MUAC > 11.0 cm; no maximum intervention period.

(4) MUAC > 11.5 cm or WHZ > -3 or no oedema (depending on admission criteria) on two consecutive visits within 12 weeks of intervention.

(5) WHZ  $\geq$  80% for two consecutive visits within 10 weeks of intervention.

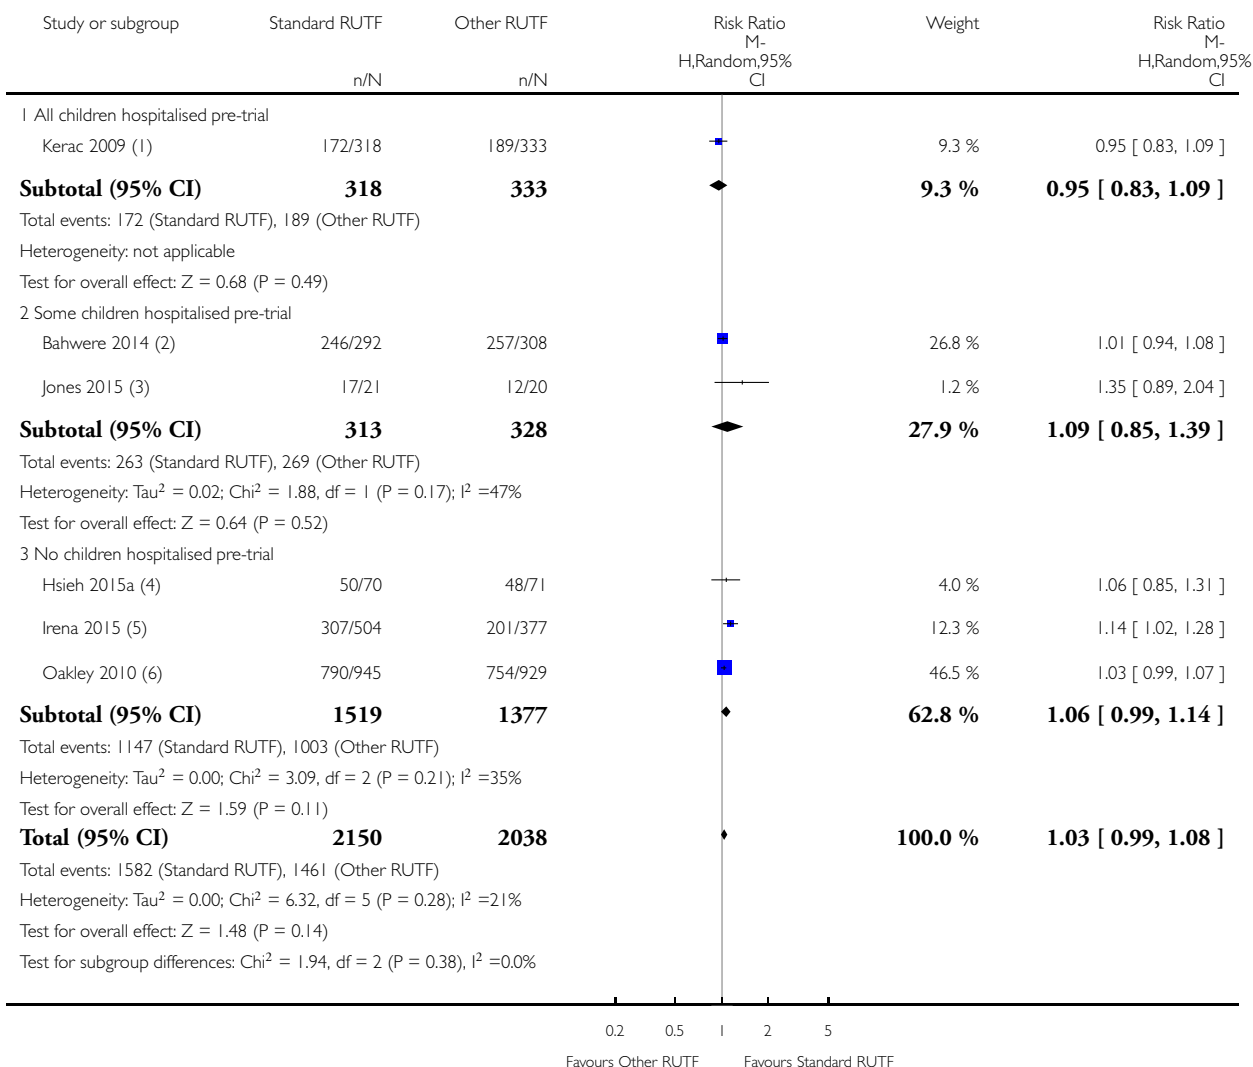

(6) WHZ > -2 and no edema within 8 weeks of intervention.

### Analysis 3.2. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 2 Recovery during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 2 Recovery during intervention: pre-trial hospitalisation subgroups

(1) WHZ  $\geq$  80% for two consecutive visits.

(2) Weight gain  $\geq$  15%, absence of medical complications and oedema, MUAC > 11.0 cm within 16 weeks of intervention.

(3) No definition provided; within 12 weeks of intervention.

(4) MUAC > 12.4 cm without oedema within 12 weeks.

(5) Weight gain  $\geq$  18%, absence of medical complications and oedema, MUAC > 11.0 cm; no maximum intervention period.

(6) WHZ > -2 and no edema within 8 weeks of intervention.

### Analysis 3.3. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 3 Relapse during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 3 Relapse during intervention

(1) Absent for 3 consecutive visits and could not be traced, or deteriorated condition and needing hospitalisation within 16 weeks of intervention.

(2) Lost to follow-up over 12 weeks of intervention.

(3) Absent for 3 consecutive visits and could not be traced, or inpatient transfer; no maximum intervention period.

(4) Lost to follow-up (including hospitalisation) within 3 months of intervention.

(5) Defaulters, readmissions to inpatient care and lost to follow-up over 10 weeks of intervention.

(6) Remain wasted after 4 consecutive visits, or clinically worsened, and referred to hospital within 8 weeks of intervention.

### Analysis 3.4. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 4 Relapse during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 4 Relapse during intervention: pre-trial hospitalisation subgroups

(1) Defaulters, readmissions to inpatient care and lost to follow-up over 10 weeks of intervention.

(2) Absent for 3 consecutive visits and could not be traced, or deteriorated condition and needing hospitalisation within 16 weeks of intervention.

(3) Lost to follow-up (including hospitalisation) within 3 months of intervention.

(4) Lost to follow-up over 12 weeks of intervention.

(5) Absent for 3 consecutive visits and could not be traced, or inpatient transfer; no maximum intervention period.

(6) Remain wasted after 4 consecutive visits, or clinically worsened, and referred to hospital within 8 weeks of intervention.

### Analysis 3.5. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 5 Mortality during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 5 Mortality during intervention

(1) Reasons for death not reported

(2) Reasons for death not reported

(3) Reasons for death obtained but not reported

(4) Most deaths related to severe pneumonia

(5) Reasons for death not reported

(6) Reasons for death not reported

(7) Progressed HIV-infection and pulmonary tuberculosis

### Analysis 3.6. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 6 Mortality during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 6 Mortality during intervention: pre-trial hospitalisation subgroups

- (1) Reasons for death not reported.
- (2) Reasons for death not reported.
- (3) Most deaths related to severe pneumonia.
- (4) Progressed HIV-infection and pulmonary tuberculosis.
- (5) Reasons for death not reported.
- (6) Reasons for death obtained but not reported.
- (7) Reasons for death not reported.

### Analysis 3.7. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 7 Rate of weight gain (g/kg/day) during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 7 Rate of weight gain (g/kg/day) during intervention

- (1) Change between baseline and 16 weeks of intervention.
- (2) Change between baseline and week 4 of 12 weeks intervention.
- (3) Change between baseline and the end of intervention (no maximum number of weeks applied).
- (4) Change between the minimum, non-oedematous, inpatient weight and 10 weeks of intervention.
- (5) Change between baseline and 8 weeks of intervention.
- (6) Using linear mixed model with adjustment over the duration of the trial and the difference between the two RUTFs.

### Analysis 3.8. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 8 Rate of weight gain (g/kg/day) during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 8 Rate of weight gain (g/kg/day) during intervention: pre-trial hospitalisation subgroups

(Continued . . .)

(... Continued)

- (1) Change between the minimum, non-oedematous, inpatient weight and 10 weeks of intervention.
- (2) Change between baseline and 16 weeks of intervention.
- (3) Using linear mixed model with adjustment over the duration of the trial and the difference between the two RUTFs.
- (4) Change between baseline and week 4 of 12 weeks intervention.
- (5) Change between baseline and the end of intervention (no maximum number of weeks applied).
- (6) Change between baseline and 8 weeks of intervention.

### Analysis 3.9. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 9 Rate of weight gain (g/kg/day) during intervention: different types of control RUTF subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 9 Rate of weight gain (g/kg/day) during intervention: different types of control RUTF subgroups

(1) Change between baseline and 16 weeks of intervention.

(2) Change between baseline and the end of intervention (no maximum number of weeks applied).

(3) Change between baseline and 8 weeks of intervention.

(4) Using linear mixed model with adjustment over the duration of the trial and the difference between the two RUTFs.

(5) Change between baseline and week 4 of 12 weeks intervention.

(6) Change between the minimum, non-oedematous, inpatient weight and 10 weeks of intervention.

### Analysis 3.10. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 10 Time to recovery (days) during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 10 Time to recovery (days) during intervention

(1) Measured across all children over 16 weeks of intervention.

### Analysis 3.11. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 11 WHZ during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 11 WHZ during intervention

(1) End value after 12 weeks of intervention.

(2) End value after 8 weeks of intervention.

(3) End value after 8 weeks of intervention.

### Analysis 3.12. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 12 WHZ during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 12 WHZ during intervention: pre-trial hospitalisation subgroups

(1) End value after 8 weeks of intervention.

(2) End value after 12 weeks of intervention.

(3) End value after 8 weeks of intervention.

### Analysis 3.13. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 13 WHZ during intervention: different types of control RUTF subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 13 WHZ during intervention: different types of control RUTF subgroups

(1) End value after 8 weeks of intervention.

(2) End value after 8 weeks of intervention.

(3) End value after 12 weeks of intervention.

### Analysis 3.14. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 14 WHZ during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 14 WHZ during intervention

(1) End value after 8 weeks of intervention.

(2) End value after 8 weeks of intervention.

**Analysis 3.15. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 15 Length/height gain (mm/day) during intervention.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 15 Length/height gain (mm/day) during intervention

(1) Change between baseline and 12 weeks of intervention.

(2) Change between baseline and 8 weeks of intervention.

(3) Change between baseline and 8 weeks of intervention.

### Analysis 3.16. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 16 Length/height gain (mm/day) during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 16 Length/height gain (mm/day) during intervention: pre-trial hospitalisation subgroups

(1) Change between baseline and 8 weeks of intervention.

(2) Change between baseline and 12 weeks of intervention.

(3) Change between baseline and 8 weeks of intervention.

### Analysis 3.17. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 17 Length/height gain (mm/day) during intervention: different types of control RUTF subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 17 Length/height gain (mm/day) during intervention: different types of control RUTF subgroups

(1) Change between baseline and 8 weeks of intervention.

(2) Change between baseline and 8 weeks of intervention.

(3) Change between baseline and 12 weeks of intervention.

### Analysis 3.18. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 18 HAZ during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 18 HAZ during intervention

(1) End value after 8 weeks of intervention.

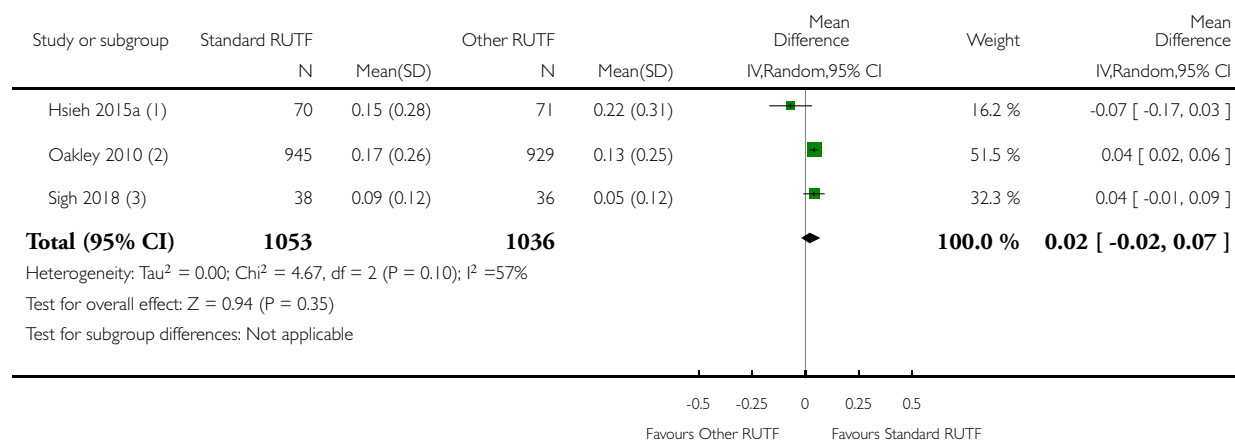

(2) End value after 8 weeks of intervention.

### Analysis 3.19. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 19 MUAC gain (mm/day) during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 19 MUAC gain (mm/day) during intervention

(1) Change between baseline and first 4 weeks out of 12 weeks of intervention.

(2) Change between baseline and 8 weeks of intervention.

(3) Change between baseline and 8 weeks of intervention.

### Analysis 3.20. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 20 MUAC gain (mm/day) during intervention: pre-trial hospitalisation subgroups.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 20 MUAC gain (mm/day) during intervention: pre-trial hospitalisation subgroups

(1) Change between baseline and 8 weeks of intervention.

(2) Change between baseline and first 4 weeks out of 12 weeks of intervention.

(3) Change between baseline and 8 weeks of intervention.

**Analysis 3.21. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 21 MUAC gain (mm/day) during intervention: different types of control RUTF subgroups.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 21 MUAC gain (mm/day) during intervention: different types of control RUTF subgroups

(1) Change between baseline and 8 weeks of intervention.

(2) Change between baseline and 8 weeks of intervention.

(3) Change between baseline and first 4 weeks out of 12 weeks of intervention.

### Analysis 3.22. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 22 Diarrhoea events during intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 22 Diarrhoea events during intervention

(1) History of diarrhoea during the first visit in intervention period.

### Analysis 3.23. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 23 Acceptability on first day of intervention.

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 23 Acceptability on first day of intervention

(1) Choosing the highest likeability score on the Likert scale.

**Analysis 3.24. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 24 Acceptability: grams of food remained after taste test.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 24 Acceptability: grams of food remained after taste test

(1) 30 g of RUTF was given to consume within 40 minutes.

**Analysis 3.25. Comparison 3 Standard RUTF versus RUTF using an alternative formulation, Outcome 25 Acceptability after first 2 weeks of treatment.**

Review: Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age

Comparison: 3 Standard RUTF versus RUTF using an alternative formulation

Outcome: 25 Acceptability after first 2 weeks of treatment

(1) A score of 1 indicated that the child liked the product very much ('very good') and 5 indicated 'very bad'.

## ADDITIONAL TABLES

Table 1. Classification of severe acute malnutrition in children under 60 months old by Collins and colleagues in 2006\*

| Severe acute malnutrition with complications  | Severe acute malnutrition without complications  |
|---|--|
| Bilateral pitting oedema grade 3 <sup>a</sup> (severe oedema)<br>OR   | MUAC < 115 <sup>b</sup> mm<br>OR   |
| MUAC < 115 <sup>b</sup> mm and bilateral pitting oedema grades 1 <sup>a</sup> or 2 <sup>a</sup> (marasmic kwashiorkor)<br>OR  | Bilateral pitting oedema grades 1 <sup>a</sup> or 2 <sup>a</sup> with MUAC ≥ 115 <sup>b</sup> mm<br>AND<br>1. Appetite<br>2. Clinically well<br>3. Alert |
| MUAC < 110 <sup>b</sup> mm or bilateral pitting oedema grades 1 <sup>a</sup> or 2 <sup>a</sup><br>AND 1 of the following<br>1. Anorexia<br>2. Lower-respiratory tract infection <sup>c</sup><br>3. Severe palmar pallor<br>4. High fever<br>5. Severe dehydration<br>6. Not alert | -  |
| Inpatient care IMCI/WHO protocol  | Outpatient therapeutic care protocols  |
| <b>IMCI:</b> Integrated Management of Childhood Illness; <b>MUAC:</b> mid-upper arm circumference; <b>UNICEF:</b> United Nations Children's Fund; <b>WHO:</b> World Health Organization   |  |

\*Collins 2006a

<sup>a</sup>Grade 1: mild oedema on both feet or both ankles; Grade 2: moderate oedema on both feet, and on lower legs, hands or lower arms; Grade 3: severe generalised oedema affecting feet, legs, hands, arms and face.

<sup>b</sup>Both the WHO and UNICEF recommend that the cut-off value for the MUAC for severe acute malnutrition is 115 mm (WHO/UNICEF 2009). Previously it was 110 mm (Collins 2006a). The adoption of this higher cut-off value will sharply increase the caseloads, which may influence the cost of nutrition programmes greatly (WHO/UNICEF 2009). However, detecting more children as severely malnourished earlier will lead to a shorter treatment period, which may bring down the cost per child (WHO/UNICEF 2009).

<sup>c</sup>IMCI criteria: 60 respirations/min for children aged < 2 months; 50 respirations/min for children aged 2 to 12 months; 40 respirations/min for children aged 1 to 5 years; 30 respirations/min for children aged > 5 years.

Table 2. Nutritional composition of ready-to-use therapeutic food, as recommended by the World Health Organization<sup>a</sup>

| Nutritional element | Amount               |
|---------------------|----------------------|
| Moisture content    | 2.5% maximum         |
| Energy              | 520-550 kCal/100 g   |
| Protein             | 10%-12% total energy |

Ready-to-use therapeutic food (RUTF) for home-based nutritional rehabilitation of severe acute malnutrition in children from six months to five years of age (Review)

|--|--|--|--|--|---|---|---|
| <b>Study period and brief comparison</b> | October 2012 - April 2015. Commercially- and non-commercially produced S-RUTF compared to energy-dense, micronutrient-enriched, locally available, home-prepared foods | December 2002 - June 2003. S-RUTF, commercially produced, versus maize/soy flour prepared by caregivers as a porridge  | March 2011- June 2013. S-RUTF, non-commercially produced, versus locally available, home-prepared foods high in energy and protein   | January-October 2001. S-RUTF, factory produced, compared to caregiver-prepared flour porridge (made from a maize and soy flour blend)  | January-September 2001. S-RUTF, factory produced, compared to caregiver-prepared flour porridge (made from a maize and soy flour blend)   | 2011. S-RUTF, non-commercially produced, "supplementary nutrition" (quote) and nutrition counselling versus "supplementary nutrition" (quote) and nutrition counselling | August 2013- March 2014. S-RUTF, non-commercially produced, versus locally available foods precooked and packaged non-commercially and prepared at home by caregivers   |
| <b>Why?</b>                              | Non-commercially produced RUTF may be less expensive and more sustainable in some countries  | To investigate whether home-based therapy with RUTF results in higher rates of recovery and lower rates of relapse or death than the (then) standard therapy in Malawi | There is a need in India for "indigenously" (quote) produced RUTF. To investigate the efficacy of such RUTF in children with SAM when compared to "standard nutritional therapy" (quote) | At the time the study started, the WHO recommended inpatient therapy until recovery for the treatment of children with SAM. For many families this was not feasible. To investigate the effects of home-based RUTF compared to ample amounts of the local staple food (porridge) in HIV-uninfected children with SAM | At the time the study started, the WHO recommended inpatient therapy until recovery for the treatment of children with SAM. For many families this was not feasible. To investigate the effects of home-based RUTF compared to ample amounts of the local staple food (porridge) in HIV-infected children (not on ARV) with SAM | To investigate the effectiveness of RUTF in therapeutic doses in community-based management of uncomplicated SAM  | There is a need in India for "indigenously" (quote) produced RUTF equivalent to the WHO RUTF recommendations. The study authors carried out a preliminary study to investigate the acceptance and efficacy of such a RUTF among SAM children in informal settlements in India |

| <b>What educational materials were provided to caregivers?</b> | Government trained health educators and promoters visited families weekly, and used site-specific counselling cards (of which the families received copies) in the local language to convey messages regarding feeding frequency, amount and how to feed the study foods; as well as on continuing breastfeeding, good hygiene and advice on family meals | Not reported.  | All caregivers were counselled about nutritional requirements and good feeding practices. However, it is unclear who performed the counselling and whether caregivers received educational material | Not reported.  | Not reported.   | Children in both groups received weekly feeding counselling at the OTP site. Unclear if caregivers received counselling material. Study staff were 2 medical doctors, 1 social worker and "angan-wadi workers" (quote) (community health workers); it is unclear who performed the nutrition counselling | All study staff (2 nutritionists, 2 anthropometrists, 3 technical assistants, 3 "lady health workers" (quote), and "4 other helpers" (quote)) were trained regarding all aspects of the study. They were also instructed to guide the caregivers (of children in both groups) regarding the schedule, method and hygienic conditions of feeding; and the cooking of the control intervention to the relevant caregivers. It is unclear whether caregivers were provided with educational material |
| <b>What procedures?</b>  | Children with SAM and without complications, or those with complications but who were stabilised first in hospi-  | All children from the maize/soy flour group and less than half of children from the RUTF group were stabilised | All children were hospitalised for 2 weeks or longer based on their complications. Study staff did not carry out  | Children with SAM were eligible, after they were stabilised as inpatients. Study staff did not make home | Children with SAM were eligible, after they were stabilised as inpatients. Study staff did not make | Children with SAM and without complications were eligible. Children who missed their weekly ap-  | Children with SAM and without complications were eligible. It appears as if no children   |

## Appendix 4. Assessment of risk of bias in included RCTs

For more information on the domains and the criteria described below, please see the *Cochrane Handbook of Systematic Reviews of Interventions* (Higgins 2017).

### Domain 1: sequence generation

Adequate: investigators described a random component in the sequence generation process such as those listed below.

1. Random number table
2. Coin tossing
3. Throwing dice
4. Shuffling cards or envelopes

Inadequate: investigators described a non-random component in the sequence generation process such as those listed below.

1. Odd or even date of birth
2. Day or date of admission
3. Hospital or clinic record number
4. Preference of the participant
5. Results of a laboratory test or series of tests

Unclear: there was insufficient information to permit a judgement of the adequacy in which sequence generation was performed.

### Domain 2: allocation concealment

Adequate: neither participants nor investigators enrolling participants could foresee assignment due to the following.

1. Central allocation (e.g. via the telephone or pharmacy-controlled)
2. Sequentially numbered drug containers of a matching appearance
3. Sequentially numbered, opaque and sealed envelopes

Inadequate: both participants and investigators enrolling participants could foresee upcoming assignment based on, for example, the following.

1. Using an open random allocation schedule
2. Assigned envelopes that were unsealed, non-opaque or not numbered appropriately
3. Date of birth
4. Case record number

Unclear: there was insufficient information to permit a judgement of the adequacy of allocation concealment in the sequence generation process.

### Domain 3: blinding

We assessed both performance and detection bias. Performance bias refers to systematic differences between groups in the care that is provided, or in exposure to factors other than the interventions of interest; while detection bias refers to systematic differences between groups in how outcomes are determined.

Adequate: when any one of the following was applicable.

1. No blinding, but review authors judged that the outcome was not influenced by a lack of blinding
2. Blinding of both key study personnel and participants was ensured, and it was unlikely that blinding was broken
3. Either participants or some key study personnel were not blinded, but the outcome measurement was blinded and the non-blinding of others was not likely to introduce bias

Inadequate: when any one of the following was applicable.

1. No blinding or incomplete blinding
2. Blinding of both key study personnel and participants was attempted, but it was likely that the blinding was broken
3. Either key study personnel or participants were not blinded, which was likely to introduce bias

Unclear: there was insufficient information to permit judgement, or the study did not address this outcome at all.

#### **Domain 4: incomplete outcome data**

Adequate: when any one of the following was applicable.

1. No missing outcome data
2. Reasons for missing outcome data were unlikely to be related to the true outcome
3. Missing outcome data were balanced in numbers across intervention groups
4. Missing data were imputed using appropriate methods
5. For dichotomous data, the proportion of missing outcomes compared with the observed event risk was not enough to have a clinically relevant impact on the intervention effect estimate
6. For continuous data, the plausible effect size among missing outcomes was not enough to have a clinically relevant impact on the observed effect size

Inadequate: when any one of the following was applicable.

1. Reasons for missing outcome data were likely to be related to the true outcome
2. Application of simple imputation was potentially inappropriate
3. An 'as-treated' analysis was done with substantial departure of the intervention received from that assigned at randomisation
4. For dichotomous data, the proportion of missing outcomes compared with the observed event risk was enough to introduce clinically relevant bias in the intervention effect estimate
5. For dichotomous outcome data, the plausible effect size among missing outcomes was enough to induce clinically relevant bias in the observed effect size

Unclear: there was insufficient reporting of exclusions to permit judgement, or the study did not address this outcome at all.

#### **Domain 5: selective outcome reporting**

Adequate: when any one of the following was applicable.

1. Study protocol was available and all of the prespecified outcomes were addressed in the review in the prespecified way
2. Study protocol was not available, but it was clear that the published reports included all prespecified and expected outcomes

Inadequate: when any one of the following was applicable.

1. Not all of the prespecified primary outcomes were reported
2. One or more of the primary outcomes was reported using measurements of analysis methods that were not prespecified
3. One or more reported primary outcomes were not prespecified
4. One or more outcomes of interest in the review were reported incompletely so they could not be entered in a meta-analysis
5. Study report failed to include results for a key outcome that was expected to be reported for such a study

Unclear: there was insufficient information to permit judgement of compliance.

#### **Domain 6: other potential threats to validity**

Adequate: the study seemed to be free of other sources of bias.

Inadequate: there was the possibility of at least one important risk of bias such as the following.

1. Quality of the specific study design was in question
2. Study was stopped early due to some data-dependent process
3. Claimed that the study was fraudulent

Unclear: there may have been a risk of bias, but either of the following applied.

1. Insufficient information to assess whether an important risk of bias existed
2. Insufficient rationale or evidence that an identified problem introduced bias

## Appendix 5. Additional assessment of risk of bias in included cluster-randomised trials

### Domain 1: recruitment bias

Recruitment bias can occur when individuals are recruited to the study after the clusters have been allocated (Higgins 2011). The types of participants recruited can be influenced by the knowledge of whether the specific cluster is an intervention or a control cluster.

1. Adequate: no participants were recruited after randomisation
2. Inadequate: additional participants were recruited after randomisation
3. Unclear: the timing of recruitment of all participants was not reported

### Domain 2: baseline imbalance

Cluster-randomised trials often allocate all clusters at once and therefore a lack of allocation concealment should not usually be a problem (Higgins 2011). However, when there is only a small number of clusters, there is a possibility of chance baseline imbalances between the randomised groups. This may affect either the clusters or the individuals.

1. Adequate: the baseline comparability of clusters was sufficient, or statistical adjustment for baseline characteristics had occurred (Higgins 2011)
2. Inadequate: there were significant differences between clusters and no statistical adjustments for baseline characteristics were made accordingly
3. Unclear: baseline characteristics were not reported, or it was not clear whether the differences between the clusters were significant

### Domain 3: loss of clusters

It is possible that complete clusters may be lost from a study, and have to be omitted from the analysis (Higgins 2011). In the same way as for missing outcome data in individually randomised trials, this may lead to bias in cluster-randomised trials. In addition, missing outcomes for individuals within clusters may also lead to a risk of bias in cluster-randomised trials.

1. Adequate: there were no missing data, or the missing data were addressed in the correct manner
2. Inadequate: there were missing data and they were dealt with in a way that could have introduced bias
3. Unclear: missing data (either complete clusters or individuals within clusters) were not reported, or it was unclear whether the authors of the primary study had dealt with the missing data adequately (e.g. acceptable statistical adjustments)

### Domain 4: incorrect analysis

Sometimes cluster-randomised trials are analysed by incorrect statistical methods that do not adjusting for clustering (Higgins 2011). Such analyses do not lead to biased estimates of effect but will get undue weight in a meta-analysis leading to overprecision of the effect estimate. Review authors can estimate an intra-cluster correlation coefficient (ICC) for such a study, and apply the design effect to the number of events and participants for dichotomous outcomes and to the number of participants for continuous outcomes.

1. Adequate: the study authors appropriately adjusted for clustering
2. Inadequate: the study authors did not adjust for clustering and there was too little information (e.g. number of clusters) available for the review authors to calculate and apply an estimated design effect
3. Unclear: the review authors applied the estimated design effect but it was unclear whether the imputed ICC and thus the design effect was close to the truth

### Domain 5: comparability with individually randomised trials

In a meta-analysis of both cluster- and individually randomised trials, or with cluster-randomised trials with different types of clusters, it is important to consider potential differences between intervention effects (Higgins 2011).

1. Adequate: the effect estimates of cluster-randomised trials were similar to those of parallel-group randomised controlled trials (RCTs)
2. Inadequate: there was a clear distinction between the effect estimates from cluster-randomised trials compared to parallel-group RCTs
3. Unclear: there seemed to be a distinction between the effect estimates from cluster-randomised trials compared to parallel-group RCTs, but it was likely that there was another explanation for the difference, other than just the difference in study design

## FEEDBACK

### Controversial sentence in Conclusion section, 3 March 2017

#### Summary

**On 3 March 2017, Professor Paul Garner (UK) submitted the following criticism to Cochrane publishers Wiley-Blackwell:**

*"In the abstract, the authors state: Given the limited evidence base currently available, it is not possible to reach definitive conclusions regarding differences in clinical outcomes in children with severe acute malnutrition who were given home-based ready-to-use therapeutic food (RUTF) compared to the standard diet, or who were treated with RUTF in different daily amounts or formulations. They then conclude: For this reason, either RUTF or flour porridge can be used to treat children at home depending on availability, affordability and practicality. However, it is not possible to reach this conclusion BASED ON THE EVIDENCE. So the evidence does not say this. The evidence says, we don't know which is best."*

**Do you have any affiliation with or involvement in any organisation with a financial interest in the subject matter of your comment?**

*"I run the RPC that helped fund this review."*

#### Reply

**On 28 March 2017, the review author team responded as follows:**

*"Thanks for the comment. We meant that, in light of the poor quality of evidence for the effectiveness of RUTF, the decision about what home-based intervention to use could be based on factors such as what is available, affordable and practical in specific settings and contexts.*

*We accept that the sentence could be incorrectly interpreted to mean that there is no difference between RUTF and flour porridge and have therefore deleted the sentence from the abstract, the plain language summary and from the conclusion. We have also begun the process of updating this review to incorporate new evidence."*

## WHAT'S NEW

| Date           | Event  | Description  |
|----------------|--|--|
| 9 October 2018 | New citation required and conclusions have changed | 11 new studies included in review. The review now has 15 included studies with 7976 children |
| 9 October 2018 | New search has been performed                      | Updated following searches in June 2017 and October 2018                                     |

## HISTORY

Protocol first published: Issue 2, 2011

Review first published: Issue 6, 2013

| Date          | Event   | Description   |
|---------------|---------|---|
| 28 March 2017 | Amended | A sentence that may have led to controversy has been removed from the concluding parts of the abstract, plain language summary and implications for practice sections |

## CONTRIBUTIONS OF AUTHORS

Anel Schoonees (AS) initiated and developed the idea. AS and Jimmy Volmink (JV) wrote the protocol, [Schoonees 2011](#), with input from Martani Lombard (ML) and Etienne Nel (EN). AS, Alfred Musekiwa (AM) and ML screened the 2017 and 2018 search outputs for eligibility and gave reasons for exclusion; the earlier search results were screened by AS and ML. AS, AM, ML and Marianne Visser extracted data. EN, AM and AS extracted economic data. AS and ML assessed risk of bias for the included studies; JV resolved disagreements. AS and ML graded the quality of the evidence using the GRADE approach. AM, AS and ML conducted the analyses and wrote the Results section with input from JV. AS and EN wrote the Discussion and Conclusion sections, with input from ML, JV and AM. EN wrote the economic commentary. EN, ML and AS put together the TIDieR tables. All review authors provided input in the final draft of this systematic review. AS is the guarantor for the review.

## DECLARATIONS OF INTEREST

Anel Schoonees - none known

Martani Lombard - none known

Alfred Musekiwa - none known

Etienne Nel has received honoraria from the following organisations in 2018 for lectures given:

- AbbVie. Topic: Crohn's Disease in Children
- Nestle Nutrition Institute in Africa. Topic: Human Milk Oligosaccharides
- Cipla. Topic: Constipation in Children

Jimmy Volmink - none known

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

The protocol for this review was published in the February 2011 issue of the Cochrane Library with the title 'Ready-to-use therapeutic food for treating undernutrition in children from 6 months to 5 years of age' (Schoonees 2011). The objectives were "to assess the effects of RUTF [ready-to-use therapeutic food] on health outcomes such as recovery rate, relapse during the intervention period, anthropometrical status, weight gain and mortality in children with moderate or severe undernutrition" (quote). Therefore, we originally planned to include children with both moderate acute malnutrition (MAM) and severe acute malnutrition (SAM), and include RUTF treatment in facilities and at home. In June 2012, the first review author (AS) presented the draft findings of this review at the South African Cochrane Centre's monthly Cochrane Busting Session, which was attended by national and international researchers doing work on priority topics in low- and middle-income countries, including Cochrane Reviews. At this meeting, questions about the scope of our RUTF review were raised. RUTF was originally developed as a home-based alternative to the more expensive facility-based treatment of children with SAM. Points raised included the following.

1. In rural areas, where people reside far from healthcare facilities, home-based treatment is more practical.
2. From a health system's perspective, it is important to know whether the cheaper RUTF regimen (RUTF as a supplement rather than RUTF meeting daily nutritional requirements) and formulation (reduced milk powder content) can achieve similar or better health outcomes.
3. From a nutritional perspective, it is important that the children's caregivers sustain and improve culture-specific dietary habits instead of relying solely on provided medical nutritional therapy.

After further discussion, including with additional stakeholders, we decided to change the scope of our RUTF review to include only home-based RUTF treatment, and to focus only on children with SAM. We assessed the treatment effects of home-based RUTF compared to the standard diet in children with SAM, and also investigated whether a cheaper RUTF treatment (in smaller amounts or using a cheaper recipe) could achieve similar health outcomes than conventional RUTE. Thus, our review did not overlap with the Cochrane Review by Lazzarini et al, which evaluated the "safety and effectiveness of different types of foods for children with moderate acute malnutrition (MAM) in low- and middle-income countries" (Lazzarini 2012; Lazzarini 2013).

Apart from changing the intended scope of the review, we also made the following small amendments to the [Types of outcome measures](#) section, when conducting the first full version of this review (Schoonees 2013).

1. We changed the first primary outcome, from "recovery rate as defined by the study authors" to "recovery as defined by the study authors", as this is a more inclusive outcome; none of the included studies reported recovery as a rate. In future, should studies provide results for 'recovery rate', we will include them in our review.

2. We added the words “and beyond” to the outcome of “deterioration or relapse during the intervention period as defined by study authors”, so that it read as “deterioration or relapse during and beyond the intervention period as defined by the study authors”. We did this because felt that relapse at follow-up was important, as it is an indication of whether the intervention has a longer-term effect.

3. We added “time to recovery (duration of rehabilitation)” as a second secondary outcome, as this is useful from both a cost and clinical perspective.

## Differences between protocol, review and this update

In 2017, when we started to update the 2013 review (Schoonees 2013), we made the following small changes.

### 1. Title.

i) We refined the title by changing “home-based treatment” to “home-based nutritional rehabilitation” of RUTF. We wanted to make it clear to the reader from the outset that we are not focusing on the ‘stabilisation’ phase of treatment, which usually requires hospitalisation.

### 2. Objectives

i) We kept the comparisons the same, but changed the order for Comparisons 2 and 3 around, so that the experimental group in all comparisons are standard RUTF. We feel, in this way, it is easier for the reader to follow.

### 3. Types of participants

i) We added another decision rule to our criteria: where a potentially eligible study randomised participants that were not all eligible to our review (e.g. included MAM children or children outside of our prespecified age range), we included the study if 50% or more of the participants met our review criteria, and we were able to obtain the separate results for our eligible subgroup.

### 4. Types of interventions

i) We updated our wording in terms of the types of experimental and control interventions. In our previous review all three included studies for Comparison 1 had the same control group and there was only one study that addressed Comparison 3. We had to change our wording to accommodate other eligible studies that used different control groups.

ii) We replaced the phrase “as defined by authors” (quote) in relation to the experimental RUTF with “meeting the WHO recommendations for nutritional composition” (quote).

iii) We added another decision rule to our criteria: where children were stabilised in hospital pre-trial and started rehabilitation as inpatients, we included the study as long as the majority ( $\geq 50\%$ ) of the trial’s intervention period occurred at home.

### 5. Types of outcome measures

i) We added acceptability as secondary outcome, as standard RUTF may not be acceptable across cultures and settings.

ii) We added time points to all outcomes, since, for example, for time to recovery and rate of weight gain ( $g/kg/day$ ), it only makes sense to measure this during the intervention period.

### 6. Electronic searches

i) We added Epistemonikos to the list of databases in order to identify other relevant systematic reviews.

ii) The Information Specialist of Cochrane Developmental, Psychosocial and Learning Problems added the MeSH term ‘food formulated’ to increase the sensitivity of search strategy.

iii) We developed a separate search strategy to find cost-effectiveness studies, and searched NHS Economic Evaluation Database and EconLit in addition to MEDLINE and Embase.

iv) We added an economic commentary in the Discussion section, as this information may be useful to policymakers.

### 7. Assessment of risk of bias in included studies

i) In our protocol, Schoonees 2011, and 2013 review, Schoonees 2013, we did not prespecify which domains we considered when assessing the overall risk of bias per included trial. For this review update, we made this decision by looking overall at the domains addressing selection bias, attrition bias (specifically large or differential attrition between groups) and ‘other bias’.

### 8. Subgroup analysis and investigation of heterogeneity

i) We added the following subgroup analyses listed below. In our previous review (Schoonees 2013), all three included studies for Comparison 1 had the same control group and there was only one study that addressed Comparison 3. We had to update our subgroups to address important difference between studies:

a) pre-trial hospital stabilisation versus no pre-trial hospitalisation; and

b) commercial (i.e. factory) versus non-commercially produced (i.e. institution kitchen) RUTF.

ii) We were unable to conduct the following subgroup analysis because of the manner in which the data were reported: Age of children: 6 to 12 months, as this is the ideal period to start weaning from a milk-based diet; 13 months to 5 years, as these children consume a mixed diet (mostly not breast milk although the child may still be taking some).

## 9. Sensitivity analysis

i) Instead of using allocation concealment as a marker of study quality, we used overall low risk of bias, as we felt that other aspects of methodological quality were equally important. This is in line with criteria 12 of the AMSTAR 2 tool (Shea 2017).

## 10. Excluded studies

i) We previously excluded Dube 2009 in our 2013 review (Schoonees 2013), because the “Outcome [was] not applicable (an acceptability trial)”. We reconsidered this trial’s eligibility for this update, as it now includes acceptability as an outcome. The study remains excluded because participants, as per Figure 1 in the article, were moderately malnourished and thus the study does not meet our inclusion criteria (Criteria for considering studies for this review).
